## \*% detected as AI

AI detection includes the possibility of false positives. Although some text in this submission is likely AI generated, scores below the 20% threshold are not surfaced because they have a higher likelihood of false positives.

### Caution: Review required.

It is essential to understand the limitations of AI detection before making decisions about a student's work. We encourage you to learn more about Turnitin's AI detection capabilities before using the tool.

### Disclaimer

Our AI writing assessment is designed to help educators identify text that might be prepared by a generative AI tool. Our AI writing assessment may not always be accurate (i.e., our AI models may produce either false positive results or false negative results), so it should not be used as the sole basis for adverse actions against a student. It takes further scrutiny and human judgment in conjunction with an organization's application of its specific academic policies to determine whether any academic misconduct has occurred.

## Frequently Asked Questions

### How should I interpret Turnitin's AI writing percentage and false positives?

The percentage shown in the AI writing report is the amount of qualifying text within the submission that Turnitin's AI writing detection model determines was either likely AI-generated text from a large-language model or likely AI-generated text that was likely revised using an AI paraphrase tool or word spinner.

False positives (incorrectly flagging human-written text as AI-generated) are a possibility in AI models.

AI detection scores under 20%, which we do not surface in new reports, have a higher likelihood of false positives. To reduce the likelihood of misinterpretation, no score or highlights are attributed and are indicated with an asterisk in the report (\*%).

The AI writing percentage should not be the sole basis to determine whether misconduct has occurred. The reviewer/instructor should use the percentage as a means to start a formative conversation with their student and/or use it to examine the submitted assignment in accordance with their school's policies.

### What does 'qualifying text' mean?

Our model only processes qualifying text in the form of long-form writing. Long-form writing means individual sentences contained in paragraphs that make up a longer piece of written work, such as an essay, a dissertation, or an article, etc. Qualifying text that has been determined to be likely AI-generated will be highlighted in cyan in the submission, and likely AI-generated and then likely AI-paraphrased will be highlighted purple.

Non-qualifying text, such as bullet points, annotated bibliographies, etc., will not be processed and can create disparity between the submission highlights and the percentage shown.

## Unit 1: Introduction to AI

### Learning Objectives:

1. Discuss what is meant by Artificial Intelligence, its history and key features.
2. Search and explain what AI is in different sectors of business (including health, finance, education, manufacturing)
3. Examine current and emergent AI trends and consider how they might affect the future of work and society.
4. Considerations about the ethics, law and society for AI technology development and deployment.
5. Distinguish how AI is used in artistic, commercial, and interdisciplinary contexts by example.
6. Consider AI's potential role in driving innovation tomorrow and develop perspectives on what this will mean for the world.

## 1.0 Introductory Caselet

### When Efficiency Isn't Enough — Aarav at QuickKart Logistics

Aarav, an engineering grad with a specialization in operations got placed for the first time at QuickKart Logistics -- a mid-sized company aiding e-commerce brands with last-mile delivery in Indian cities. The QuickKart had been known for its speed, but with the economy in free fall — and higher fuel costs leading to less predictable delivery times — customer gripes were eroding its profits.

The COO posed one obvious question in an internal strategy session: “How,” he asked, “can we do it faster, cheaper and smarter”?

— without frying our labor force?

Aarav the curious tech trend explorer had recently read something on an AI in logistics. He had no background in computer science; he started looking at how AI was being applied elsewhere across other logistics giants. He discovered that real-time route optimization algorithms, predictive demand forecasting and even chatbots driven by artificial intelligence were reducing the burden on customer service.

It could use AI to design routes through a metro city. With the aid of a tech consultant, Aarav created an artificial intelligence system that relied on real-time data about traffic, weather and number of deliveries to make delivery route recommendations. Within six weeks they had cut delivery times by 22%, while the number of customer complaints had fallen and fuel costs went down by 15%.

Leadership was wowed and the company approved a phased pilot across several cities.

It changed Aarav's mindset on machine learning. It was not just a “tech thing” — rather, it was a superpower that would let us make better decisions faster, designed to speed up business and open up unprecedented new frontiers in every field.

Critical Thinking Question:

How would you actually convince someone who's a traditional operations manager in a building that could be 100 years old that AI is not just another form of automation — it's not putting everybody out on the street and replacing everybody with technology?

a tactical artillery to better the consumer experience, reduce cost and out compete?

## 1.1 Introduction to Artificial Intelligence

### 1.1.1 Definition and Meaning of AI

AI stands for 'artificial intelligence', a sub-field of computer science concerned with constructing systems to perform tasks which would normally require human intelligence. These tasks consist of reasoning, problem solving, learning from experience, comprehension of natural language and perception of the environment. The big dream behind AI is to build both machines and software that can mimic or even simulate intelligent behavior in order to solve difficult problems, but in a smart and scalable way.

The earliest usage of the term “Artificial Intelligence,” can be dated back to 1956 by John McCarthy at the Dartmouth Conference – an event now commonly referred to as the birthplace of AI as an academic field. Since then AI has expanded to include many areas of computer science, psychology, neuroscience, linguistics and philosophy.

Artificial Intelligence can generally be classified among the following subfields:

## AI can be broadly categorized into the following subfield

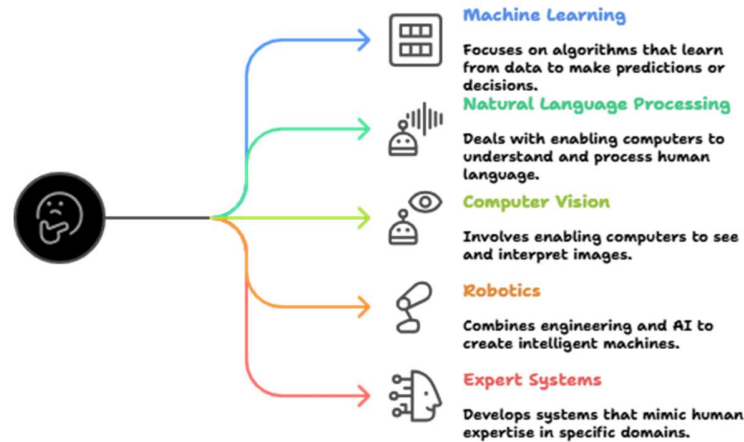

Figure: AI can be broadly categorized into the following subfields

Machine learning (ML): Aims to generate algorithms and models capable of allowing a computer to learn from data as well as make decisions.

Natural Language Processing (NLP) : NLP helps machines understand, interpret and generate human language.

ComputerVision: Enable systems to sense and understand visual information in the world.

Robotics: Design of intelligent systems that are capable of carrying out physical tasks.

Expert Systems: Simulate reasoning of human experts in certain domain.

It is also important to differentiate the three related terms that are often intermixed:

AI: A general area of research that includes as one component the theory and development of computer systems which are capable of "human-like" intelligent behavior.

Machine Learning (ML): An AI subset that allows systems to learn from data.

Deep Learning (DL): A niche subfield of ML, that uses neural nets with a large number of layers (typically > 65) and processes data in a non-linear fashion.

AI goals may range from narrow AI—task-specific (e.g., image classification, voice recognition) to general AI seeking to recreate generic human cognition in different domains. Though narrow AI is already included in

### 1.0.2 History and Evolution of AI

These ups and downs that Acemoglu describes are also reminiscent of the cycle endemic to the history of Artificial Intelligence. It can be followed develop through a number of important periods:

### 1.1.2 Historical Background and Evolution of AI

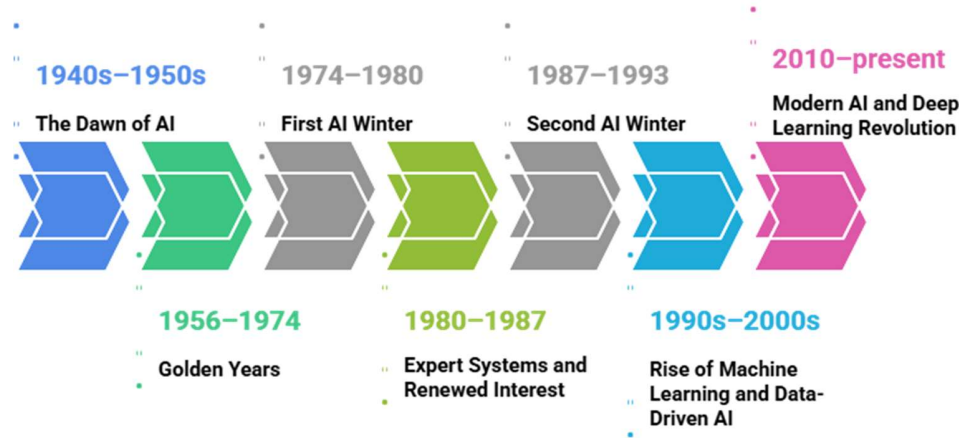

Figure: Historical Background and Evolution of AI

### Philosophical and Conceptual Foundations

Well before there was AI in its current sense, classical humans such as Aristotle, Descartes and Leibniz thought about human reasoning and intelligence and the feasibility of mechanical thinking. These early thought experiments set the stage for thinking of intelligence as a procedure, and one that might at least in principle be implemented by machines.

The 19th century mathematician George Boole created the Boolean algebra, a system of logic that would eventually prove crucial to computer science. Early thinking about programmable machines was also done by Charles Babbage and Ada Lovelace, which in turn paved the way for computational theories of intelligence.

#### a. Early AI (1940s–1950s)

The roots of artificial intelligence are ancient, but the formal roots date back to mid-20th century with the rising of electronic computing and its underlying theory of formal logic. The notion is associated with the so-called church-Turing thesis, and was originally introduced in support of the computational model advocated by Alan Turing — considered since then one of forefathers of theoretical computer science and artificial intelligence — who

conjectured existence of a universal machine that could simulate any computation. In his famous 1950 paper, "Computing Machinery and Intelligence," Turing conceived the Test - a test is that a human judge engages in natural language conversations with two other parties, one a human the other its machine counterpart, both of them are hidden from view.

Creation of field The Dartmouth Conference in 1956 was the first AI conference and was held at Dartmouth College; it was organized by John McCarthy (computer scientist), Marvin Minsky, Nathaniel Rochester, and Claude Shannon (and considered by some as the origin of AI as a field). The participants declared that "every aspect of learning or any other feature of intelligence can in principle be so precisely described that a machine can be made to simulate it."

#### b. Golden Years (1956–1974)

During first AI programs proved effective at solving algebra problems, proving geometric theorems and playing simple games with rudimentary rules (like chess). Key developments included:

- Logic Theorist (1956) – Developed by Newell and Simon, It could prove mathematical theorems.
- General Problem Solver (1957): Responsible for solving problems in general by means of formal logic.
- ELIZA (1966): One of the earliest natural language processing programs, a simulation of a psychotherapist.

Although early progress was promising, these worked poorly and were based heavily on hard-coded rules that made adapting both complex real-world tasks impossible.

#### a. First AI Winter (1974 - 1980)

But funding and excitement for AI diminished in the mid-70s, when early systems failed to scale up and deal with ambiguous real-world input. A.I. Project The U.S. and U.K. governments cut funding for research in artificial intelligence, precipitating what was referred to as the "AI Winter."

#### b. Expert systems and the popularity regained (1980–1987)

The 1980s ushered in the resurgence of AI (symbolized by Shakey the Robot), largely due to the successes of expert systems, including XCON used by DEC. These systems simulated problem-solving in narrow domains based on large rule databases. For a time, they were commercially viable and attracted corporate investment.

But expert systems were fragile, costly to maintain and unable to learn on the job. This triggered another phase of diminution in the late 1980s.

A second AI Winter occurred due to the failures of rule-based agents and increased expectations. Dozens of companies pared back or killed off their A.I. projects. But some early-stage work did stay on course in areas like statistical learning and neural networks, which would pave the way for breakthroughs to come.

#### d. Rise of Machine Learning and Data-Driven AI (1990s—2000s)

Similarly, big data, increased computational capacity and new algorithms in the 90s revitalised AI. AI was moving from logic-based systems to data-oriented ones. Key milestones included:

- Decision Trees, Bayesian Network and SVMs
- IBM's supercomputer Deep Blue defeating world chess champion Garry Kasparov in 1997

#### a. Contemporary Ancient and Present AI (from 2010 onwards)

AI's 2010s were shaped by deep learning breakthroughs – what will the next decade bring? With architectures like CNNs and RNNs, came the rise of AI to be better than humans in some responsibilities like image recognition and speech to text.

Landmark developments include:

- ImageNet Challenge(2012): deep learning unlocks image classification with AlexNet.
- AlphaGo (2016)This project, built by DeepMind, trounced the world champion Go player Lee Sedol, delegating big-picture decision making.
- GPT series (2018–present): General-purpose large language models have shown to be effective on various natural language processing tasks as text generation, translation, summarization, and inference.

But it's simply taken for granted today that recommendation engines, self-driving cars health diagnostics, financial forecasting and content generation will be augmented by AI.

### 1.0 Core Features of AI Systems

AI software systems have several unique properties that separate them from traditional software. This makes them appropriate for smart task performance and behavior in dynamic environments:

### a. Learning

A defining characteristic of AI systems is that they can learn from data and improve their performance without being programmed explicitly. Learning can be categorized into:

- Supervised learning: The systems learn from labeled data.
- Unsupervised learning: Systems discover patterns in unlabeled data.
- Reinforcement learning: Systems learn by interacting with some environment, and receive feedback in the form of rewards or penalties.

Learning is the bedrock of contemporary AI in areas like image recognition, natural language processing and game playing.

### b. Reasoning and Inference

The AI system is programmed to deduce new facts based on basic statements by the means of logical rules and heuristic. This ability gives them the opportunity to make decisions on ambiguous grounds and infer some results which are not explicitly given in data.

For example, expert systems can model human decision-making with logic and are a common tool in medical diagnosis and artificial intelligence.

### c. Problem-Solving

AI systems can break down complex problems into simpler sub-problems, search for optimal solutions and use general heuristics. State-space search, A algorithm\*, and constraint satisfaction are well known AI planning and robotics techniques.

Sophisticated problem-solving AI is now on display in machines like AlphaZero, a system that — starting from first principles — learned to master perfect play of games such as chess or Go.

### d. Perception

Perception Abilities: This is how AI system 'sees' and the way to make sense of visual, audio, touch etc so that it can see or hear as clearly. Key technologies include:

- Computer vision: Object, scene and facial recognition.
- Speech-to-text: The process of recognizing spoken language and transforming it into text.
- Sensor fusion: Combining inputs from different sensors (LIDAR, cameras) in self-driving cars.

Perception is indeed the number one AI problem for these real-world systems — drones, robots and self-driving cars.

#### e. Natural Language Understanding and Generation

NLP, standing for natural language processing, means to which the AI can understand and process human text or speech — so not just translate from one language to another. That’s learning your syntax and semantics and pragmatics.”

New developments in large scale NLP modeling have significantly strengthened AI’s ability to:

- Summarize documents
- Answer questions
- Generate inventive, unusual or curious messages
- Transcend languages

The capabilities in language are central to virtual assistants, customer service bots and AI for education platform.

#### a. Autonomy and Adaptation

AI systems are self-contained and do not need humans to run. This is even more important when you are working with things like robotics, finance trading or self-driving cars where you need to make instant decisions.

Adaptation allows AI to respond to changing environments and learn from new data. For instance, recommendation students’ progress.

#### Industries Adopting AI

##### 1.1.2 Introduction to Industries Adopting AI

AI has matured out of the halls of academia or tech-side silos and into a core technology for various industries of commerce. Driven by the rapid increase of data and widespread..

the coupon books and gut-wrenching real-time decisions artificial intelligence is reprogramming the market landscape from health care to ride hailing.

Businesses are adopting A.I. to not only automate repetitive tasks but also help make better decisions and jump-start growth — its own, and that of customers. AI (and its child technologies machine learning, NLP & computer vision)

ingested centuries old practices and workflows, decimated pre-millennial business models on its way to sticking the landing firmly in toddlerhood of the 'Fourth Industrial Revolution,' as some have labelled it.

While competition in the world become more a struggle, Industry driven by AI technology continue to be still ahead in Technology development and productivity & service offering. What it means for the future: National governments and global Goliaths are pouring money into A.I. R&D, having caught a glimpse of ways in which they can remake everything from economic systems to workforces to technologies based on artificial intelligence.

### 1.1.3 AI in Healthcare

Healthcare is one of the most active domains where we see the application of AI techniques. AI is changing the face of healthcare from diagnosis to planning treatment and has been proven to offer new solutions that help deliver better patient outcomes.

#### Medical Imaging and Diagnostics:

AI algorithms – especially those based on deep learning – are now good enough to accurately analyze medical images, matching or exceeding the performance of radiologists. For instance, convolutional neural networks (CNNs) are used in the interpretation of X-rays, CT scans and MRIs to identify tumours, fractures and other abnormalities. Google's DeepMind, for example, trained A.I. models that can identify more than 50 eye diseases as effectively as leading ophthalmologists.

#### Predictive Analytics and Preventive Care:

AI systems are now being used to forecast outbreaks, identify high-risk individuals and advise about early interventions. Machine learning models scan electronic health records (EHRs) to identify suspected maladies such as heart attacks or sepsis before the onset, to timely administer an appropriate medical response.

#### Personalized Medicine and Drug Discovery:

Genomics and patient history By reviewing genetic data and patient medical history, AI can help personalize treatments to the needs of individual patients. Companies such as IBM Watson Health and BenevolentAI employ AI to speed up drug discovery, finding promising compounds and recommending potential therapeutic uses.

#### Virtual Health Assistants and Administrative Support :

AI chatbots and virtual assistants are used to patient queries, schedule appointments, and even monitor chronic conditions. This reduces the burden on healthcare professionals while enhancing accessibility and responsiveness.

#### “Activity”

Get a sample dataset of patient 'symptoms' and associated 'diagnoses' (you can use public/simulated data). Provide

10. Turnitin including symptoms (eg fever and cough, myalgia, rash, sore throat) and diagnoses (flu vs allergy vs

COVID-19). Train a simple AI model to diagnose diseases by symptoms (using an easy no-code AI tool like Teachable Machine from Google or Microsoft Lobe). Feed your data set, train the model and get it to test with new sets of symptoms. Verify, and report any mis-classifications. Hand in a short report with a description of the training course, the results and one real-life difficulty to using AI for clinical diagnosis.

### 1.1.4 AI in Finance and Banking

The financial sector is one of the earliest adopters of data-driven innovation, and AI is pushing this trend even further. The predictive and automation capabilities of AI are contributing to enabling smart financial services, effective risk management and client engagement.

#### Fraud Detection and Risk Assessment:

AI algorithms are programmed to search for the abnormal data, or patterns of data that deviate from the norm and that could be indicative of fraud. For example, AI-driven algorithms analyze transactional data looking for anomalies when saving while alerting in the event of anomaly withdrawals or if abnormalities are detected in an account-opening process. Machine learning models also help credit scores assess credit risk using alternative data points, such as online activity or transaction history.

#### Algorithmic and High-Frequency Trading:

It is also used in stock trading, with AI using market data, news and financial reports to make rapid trades. These platforms digest information far faster than a human trader and can make buy/sell orders in milliseconds.

#### Credit Scoring and Loan Underwriting:

Conventional credit scoring can be a blunt instrument that shouts past non-traditional borrowers. AI PURPLE 82231387-5 - add on to the credit appraisal by utilizing integrated and processed based networked avatars mobile footprint information and social profile data, transaction history etc enhancing the financial inclusion borrower(s) 71.

#### Customer Service and Chatbots:

Bots in Banking and Finance Banks and finance companies rely on AI-driven chatbots to answer typical customer questions, help users navigate transactions, or lend financial advice. These systems are available 24/7 which leads to great customer service ratio.

## 1.1.5 AI in Education and Learning

Artificial Intelligence is changing the way we learn making education more personal for each student. Artificial Intelligence is making learning more efficient. Artificial Intelligence is also making education more inclusive.

There are applications for Artificial Intelligence to be deployed such as smart tutoring systems that assist students to learn. Teachers can also benefit greatly from this, if the computerized automation is incorporated in Artificial Intelligence. In other words, this opens up the possibility for AI to enhance how students learn as well as how teachers teach.

### Intelligent Tutoring Systems (ITS):

These systems can tailor learning for every student. They do so by modifying how they teach and support students according to how students learn, like to learn and what they need. For example some computer programs such as the one made by Carnegie Learning use techniques to determine what each student needs. This enabled them to provide students with problems they need work on; explanations that make sense for them; and tests that reflect what they know. Carnegie Learning and any other program similar to it are very helpful, at teaching us because they focus on what each student has a problem with/needs.

### Personalized Learning Pathways:

So long as we have data about our students, data that can be input into AI algorithms, we can use the latter to recommend what students should learn, based on what they are good at and not so good at. This method for teaching, where the student data is used to personalize learning really makes students engaged and continue to learn even when they aren't in a seat inside of a classroom. The student data is also extremely important for the AI algorithms to generate these suggestions and so this student data actually helps the AI algorithms in understanding what each student needs to learn.

### Automation of Administrative Tasks:

A.I. systems are great at tasks like grading and scheduling. They can also assist in managing resources.

Artificial Intelligence systems and Natural Language Processing or NLP, for short can be used to score essays. This means that Artificial Intelligence systems and NLP can read a student's writing and give them feedback quickly in just a few seconds.

### Learning Analytics and Performance Prediction:

Schools leverage AI to identify patterns in student achievement, forecast drop-out rates and act in advance. AI-informed dashboards give teachers real-time views of class engagement and understanding levels.

## AI in Manufacturing and Retail

Artificial Intelligence is also helping to make manufacturing and more digital. This helps to make things more efficient reduce costs and create ways for customers to experience things. Artificial Intelligence is really changing the way manufacturing and retail work making it better, for everyone, the customers.

### Predictive Maintenance:

Machines have sensors that give us data. AI models look at this data from the machines to figure out when the machines will break. This is called maintenance. Predictive maintenance helps to reduce the time the machines are not working. It also helps the machines last longer. Gives us more time to fix them when they do break. Predictive maintenance is important, for the machines. It helps us to do repairs at the right time.

### Quality Control and Defect Detection:

Computer vision systems that use intelligence can find problems in things that are being made better or faster, than any person. These systems are used in places that make electronics, cars and medicine.

### Supply Chain Optimization:

Artificial Intelligence also helps with supply chains that can change quickly and easily. Artificial Intelligence does this by figuring out what people will want to buy so companies do not have many things in stock that they cannot sell. Artificial Intelligence helps with the supply chains in these ways:

- \* it predicts what people will want to buy

- \* it reduces the amount of things that companies have in stock.

Establishing Nimble and Adaptive Supply Chain with Reduction in Overheads Using AI-friendly – Cloud Computing  
Artificial Intelligence powers flexible supply chains that can change themselves when it demands on them. This is good on several fronts, for companies as well because an A.I. program can predict when demand will take off and curtail overproducing goods — and that makes a company more environmentally friendly, along with more profitable.

Firms are refining logistics routes. They rely on demand-sensing algorithms to assist them in making adjustments to inventory levels when it's appropriate to do so. These algorithms read signals, from the market. That helps routes for logistics to be optimized. "Logistics routes are very important and logistics route optimization can impact," he said.

### Customer Behavior Prediction in Retail:

Companies such as Nike and Macys utilise Artificial Intelligence software to see what people have bought, what they usually look at on the internet, and what users post on social media. This is what helps Nike or Macys know what a consumer is probably going to want. Then they can put their marketing muscle behind the consumer, if you will.

There are some examples of this like the recommendation engines that Amazon and Netflix use. Amazon and Netflix are really good, at using these engines to show people things they might like.

#### Robotics and Automation in Warehousing:

AI-imbued robots glide through warehouses, sort inventory, pack orders and more. Retail whales like Walmart and Alibaba leverage AI-powered robots to accelerate order fulfillment and delivery.

#### Transportations and Smart Cities using AI

The AI Revolution in Transportation and Urban Development It's improving so we can at least get around. And it is helping us move forward on things like mobility, how infrastructure works and how our cities are governed." AI is transforming the very way that we think about governing cities.

#### Autonomous Vehicles:

Intelligence algorithms help autonomous cars make decisions based on data from sensors, cameras and GPS coordinate services that answer questions like, "What is the maximum number of ways out, shortest path distances to those exits from multiple realistic points at which it would be safe for the car to stand still during testing?"

Tech companies like Tesla, Waymo and Uber Technologies are investing heavily in cars that a driver may never have to touch.

This is going to completely change how people use cars to get around.

#### Traffic Management Systems:

They're even using AI to track harmonize traffic signals and reduce congestion as the situation changes

We have robo traffic lights, AI-driven and if it's busier on differences of densities of the cars in motion, people moving that really is a better performing of traffic.

### Smart Infrastructure and Energy

Efficiency In cities for instance AI is used to control resource such as water and electricity. It does so by determining how much of these kinds of things we will need, and then ensuring that they get to the places where they are needed. The lighting and heating and cooling systems that run buildings also rely on Artificial Intelligence. This is one way to conserve energy in these buildings. Artificial Intelligence is very good, at getting smart cities to work better.

### Surveillance and Public Safety:

There are so many surcams used in the cities to watch people. It can spot people who are acting weird or suspicious manage crowds and determine what's going on when something seems suspicious. It knows who people are for the purposes of security.' As we can see, with all the good things SRFGS can do there are also some serious problems. SRFGS raises ethical and privacy issues.

### Urban Mobility and Public Transport:

Intelligence led analytics can actually help us design better public transport networks. It is because it learns where the gaps are in the service, then predicts what people will need. If you track where all the people are going using AI then public transport networks can be made efficient. AI is used by ride share apps like Uber and Lyft for the self-organizing dispatch system, pricing algorithm, and routing algorithm.

## AI in E-Commerce

By Wilby Carlson, 5th December Even when artificial intelligence may not be the most obvious choice of technology for online shopping it can provide a more personal experience It can make jobs more efficient It can maintain interests campaigns. One possibility is that when online stores employ AI algorithms, it can be easier for customers to shop and the work they're doing behind the scenes becomes easier.

### Personalized Recommendations:

AI-driven recommendation engines watch what customers do who they like and what they buy. They leverage this knowledge to recommend products that are alike or complimentary to what people already like. These are systems that go through a set of different means to determine what kinds of groups of people do, or what shared items amongst those groups, and try to optimise that search for things so the shopping experience is better for everyone. This helps encourage more people to buy things and results in customers being happier with their shopping experience. Artificial intelligence-powered recommendation engines are quite good at helping to make shopping easier and more fun — enjoyable, not frustrating — for customers.

### Dynamic Pricing and Inventory Management:

Companies can change their prices frequently thanks to artificial intelligence. This is because they can see what demand looks like and what their rivals are up to. They can also monitor what and how much of their in-stock items they have.

Artificial intelligence helps businesses make the money by changing prices automatically. This happens in time so companies can respond quickly to what is going on.

At the time artificial intelligence models try to figure out how many items a company will need. This helps them avoid having many or too few items in stock. Artificial intelligence does this by predicting what the company will need so they can stay on top of things. Avoid problems, like running out of stock or having too much stock.

#### Visual Search and Chatbots:

The AI-based visual recognition system lets the user search, for a product using images of typing the text.

AI chatbots are available all the time to help the user. They respond to questions handle returns and assist the user when they are buying something.

This means the user gets customer service from the AI-based visual recognition system and the AI chatbots.

#### Fraud Detection and Transaction Monitoring:

It catches fraudulent transactions with machine-learning algorithms that search for abnormalities in buying and payment patterns. These systems are learning-based and iterate from new data to improve their detection accuracy as well as reduce false positives.

#### AI in Social Media

How AIs are influencing today's social media: Not just for delivering and moderating content, but also for sentiment analysis and behavior profiling.

#### Content Recommendation and Feed Personalization:

Facebook, Instagram and TikTok have intelligence. They remove a lot of content. Facebook, for instance, takes down roughly 3 billion pieces of content every quarter. This is because the content violates rules about hate speech and other bad things.

Facebook, Instagram and TikTok all employ computer programs that learn and improve over time. Those programs observe what users like. Do not like. Then, they display Facebook, Instagram and TikTok material for users that they believe they will love. It's a way of keeping users on Facebook, Instagram and TikTok.

#### Automated Content Moderation:

The reason is that A.I. models are trained to find hurtful things, from hate speech to naked pictures and other violent stuff. Systems for Natural Language Processing and image recognition that could be trained to recognize or filter such a content, allowing sites to enforce the rules they've developed for their community and meet their legal obligations. AI models are being put into service to recognize hate speech, nudity and acts of violence in order to prevent further harm befalling people on the internet.

Artificial Intelligence technology reads what people write in their posts and comments, taking the public temperature on brands, current events or hot social issues. It is gold for firms and government people who seek to know what the public thinks about something right now. The A.I. tech is good at detecting the moods underneath those brands and events and social issues. Businesses use it to make decisions, and government officials spy on it to learn what the public is talking about.

Deepfake Detection and Misinformation Control:

As the AI-made-misinformation threat matures, social media networks are deploying counter-AI tools to generate warnings about faked content — a sort of machine-beats-machine version of cat and mouse in which machines may for now be holding the edge over humans. Approaches such as deepfake detection models are able to control exposure of fake news.

### AI in Technology and Communication

In technology and telecommunications Artificial Intelligence is making systems work automatically it is making networks better. It is also improving the way computers and people talk to each other. Artificial Intelligence is really changing the way things are done.

Network Optimization and Predictive Maintenance:

Carrier companies use intelligence to manage the bandwidth figure out when the network might get too busy and take care of maintenance work on their own.

The thing that really makes a difference is monitoring. It is really helpful even when it is used by itself.

The special algorithms that predict what might happen can stop the system from shutting down by finding errors when they're still small. Carrier companies, like these algorithms because they help prevent downtime. Carrier companies use them to keep the network running.

NLP in Communication tools:

Artificial intelligence makes digital communication better with things like real-time transcription, translation and figuring out how people feel.

Apps like Google Meet, Zoom and Microsoft Teams use speech recognition and natural language processing to make things easier, for users and help everyone use them.

CaS - Automated Customer Support and Unattended Agents:

Agents based on Artificial Intelligence are used by telecommunication companies and technology solution partners to deal with customer service of troubleshooting and technical support for normal issues. These virtual agents (such as

the former) follow rule-based systems, where rules can be visualized as decision trees. Considering the context for the right resolution. They apply decision trees and context analysis to ensure they fix the problem correctly which is what virtual agents should do if you're providing customer service or technical support.

#### AI in Software Development:

Other use cases for AI include code generation, bug finding and software testing. Tools like GitHub Copilot use transformer-based models to suggest code snippets and improve the productivity of developers.

#### AI in Travel and Navigation

There's been a lot of brainstorming around travel and transportation, because obviously AI is being applied to things like which are the best routes to take but how do you make the experience great for humans, for customers. A.I. is really revolutionizing travel and transportation in ways such as making the customer's journey more fun."

#### Travel Assistants and Booking Platforms:

AI powered chatbots and virtual assistants are making it easier for people to book trips. They accomplish this by providing users the travel ideas that are perfect for them. These theories rely on what the user can afford, preferences and system loyalty.

For instance sites like Expedia and Booking.com to help ease trip planning. Artificial intelligence is used by these platforms to provide what users need in order to plan a trip. AI driven chatbots and bots in general are really great, at this.

#### Dynamic Pricing in Airlines and Hotels:

Airlines and hotel chains are using Artificial Intelligence to figure out the prices based on how many people want to travel what time of year it is, what their competitors are charging and when people usually make bookings. This helps them make money by changing their prices at just the right moment. Airlines and hotel chains really like this system because it helps them make the most of Artificial Intelligence and get the results, from their pricing.

### Navigation and Traffic Optimization:

AI-powered navigation systems such as Google Maps and Waze process traffic, road closures and user comments to suggest the ideal route. Machine learning algorithms forecast and preempt future traffic for predictable routing.

### Facial Recognition and Security Screening:

Facial recognition An AI-powered facial recognition system helps airports identify passengers and get them on planes faster. These systems enhance security, diminish down time and also make it possible for no-contact travels.

### AI in Smart Home and IoT

Artificial Intelligence mixed with Internet of Things is really changing our world.

Now our homes and offices are becoming spaces.

These spaces can adjust on their own to how people live and work in them and, to what's happening around them.

Artificial Intelligence mixed with Internet of Things is making this all possible.

### Smart Assistants and Home Automation:

Pucks like Amazon Alexa, Google Assistant and Apple Siri can understand what we say and help us control our home systems. Amazon Alexa, Google Assistant and Apple Siri get better at helping us over time. This is because Artificial Intelligence helps Amazon Alexa, Google Assistant and Apple Siri learn from the way we use them so they can be more useful, to us.

### Energy Efficiency and Environment Control:

AI systems monitor how people use buildings. They gather all sorts of data about the environment within a building. They then employ the data to conserve energy for things like heating, lighting and cooling.

So the controls on these systems are super flexible. For example, a product like Nest can learn your schedule. So when you wake in the morning and are preparing yourself for a day ahead, the interior temperature can be comfortable.. As you leave for work or running to some tasks outside of your home it can once again adjust temperature to save energy. AI systems, such as Nest are pretty smart. They can have a big impact on how we handle energy in our buildings

### Home Security and Surveillance:

These cameras and sensors that use intelligence can see when someone is moving around in a weird way they can tell who people are and they send out warnings right away. They also let people watch what is going on from another location and the cameras and sensors can be connected to security systems that do more things to keep people safe.

### Predictive Maintenance of Appliances:

Smarthome-connected devices can tell when Smarthome-connected devices have issues, with how appliances work and then warn the consumer before any problems happen. This helps Smarthome-connected devices make appliances longer and it also helps the consumer save money on fixing appliances.

The artificial intelligence that is used in cybersecurity is a cool thing.

#### 1.0.1.

Artificial Intelligence is used a lot these days in defense. It helps to build capabilities such as detecting threats in time. Artificial Intelligence also does the analysis of behaviors.. It can even respond automatically. Artificial Intelligence is really useful, in defense.

### Anomaly Detection and Threat Prediction:

AI models look at network traffic and user behavior and system logs to find things that're not normal. These special algorithms that find patterns are really good at catching new threats that happen suddenly and have not been seen before so they do not have a signature that we know about yet. AI models are very useful, for finding these kinds of threats.

### Malware Analysis and Intrusion Detection:

Artificial intelligence can look at so much code. How systems cooperate to detect these bad patterns and shut them down before they can get into your systems. AI systems that identify intrusions. Improve as attackers find new

## Phishing Detection

### Email Filtering:

Artificial intelligence is really good, that is to say, at finding patterns of what the malware reveals it will do, and then stopping them. Artificial intelligence allows systems that detect intrusions to get smarter and adjust with the methods people use to attack.

Humans are relying on natural language processing to scan for messages that look off. They search for signs in language style, behavior and metadata. That helps them determine what is true and what isn't. They want to avoid messages and phishing attacks. Natural language processing is awesome, at least in finding these messages and phishing attacks.

### Automated Incident Response:

This self-healing: if a security breach is detected, AI systems can take action autonomously such as putting an infected machine in quarantine or revoking user rights. This prompt response helps ensure that hackers can do as little harm as possible. AI in Agriculture

AI is redefining agriculture by increasing productivity, optimising resource use and addressing the challenges of global food security.

### Precision Farming and Crop Monitoring:

Drones and A.I.-guided sensors gather information about soil health, the progress of crops and moisture levels. This retention is relied upon by machine learning models to recommend when and how much to water, fertilize and fight pests.

### Yield Prediction and Disease Detection:

Then artificial intelligence systems are chewing over data on sunlight and rainfall, as they try to forecast crop yields or spot incipient signs of disease or pest infestation before any farmer can. Preventing a loss and promoting sustainable agriculture.

### Automated Machinery and Robotics:

Self-driving tractors, harvesters, and planters utilize AI driven navigation and task-performing abilities to save on labor costs while increasing productivity. AI-powered robots can also be used to kill weedy tasks with dogmatic efficiency.

## Supply Chain and Market Forecasting:

AI informs farmers by predicting market demand, pricing trends and even weather effects. This helps in proper planning and minimizing post-harvest losses.

### Did You Know?

“In precision farming, AI-driven drones do more than just aerial map — they identify plant diseases, nutrient deficiencies and even soil health by analyzing leaf color spectrum and moisture data. Now, this can help farmers to know where to take targeted action, right down to the square metre of a field.

### 1.1.6 AI in Entertainment and Media

The SA says that the entertainment and media sector uses Artificial Intelligence to give people value by making better content getting it to them in a better way and changing how people interact with the entertainment and media sector.

#### Content Recommendation Engines:

Streaming services like Netflix music services like Spotify and video platforms like YouTube are using Artificial Intelligence to figure out how people watch and listen to their stuff. This helps them suggest things that people might actually want to see or hear so people will keep coming to Netflix, Spotify and YouTube to watch and listen to more content. They want to know what people like so they can give them more of the same. That is why they are using Artificial Intelligence to understand how people consume their content, on Netflix, Spotify and YouTube.

#### AI-Generated Content:

Generative Artificial Intelligence has also led to the development of music and art and scripts and news articles. Tools, like

OpenAIs DALL·E and GPT series can make text that sounds like a real person wrote it. This text can be about lots of things and have many different formats. OpenAIs DALL·E and GPT series are really good at making human-like content, in many areas.

#### Audience Analytics and Targeted Advertising:

Artificial Intelligence processes information about people like what they do and where they're to show them ads that are just right, for them and to figure out what viewers like. This helps people who make content and advertisers make their ads work better.

#### Video and Audio Enhancement:

AI algorithms do a lot of things to make videos better. They make the video resolution bigger. They get rid of background noise that you do not want to hear.. They add special effects to the videos after they are made.

AI algorithms can also translate what people are saying in time. They can make subtitles for videos fast. This helps people, around the world understand what is going on in the videos. AI algorithms really help people reach the world with their videos.

## Deepfake Technology and Virtual Actors:

While contentious, AI makes hyper-realistic VR actors and deepfake videos for fun. These emerging technologies pose ethical concerns but also create novel creative opportunities for cinema and digital media.

## AI in Human Resources & Recruitment

AI systems have changed the way we do things in Human Resources and recruitment. They have brought in a way of finding and keeping good people making sure employees are happy and managing the workforce. AI makes things easier and by automating tasks that used to be done by hand and were often biased. AI systems make these tasks more objective and efficient. AI systems are really good, at making recruitment and Human Resources tasks easier and more efficient.

**Resume Screening and Candidate Matching:** Artificial Intelligence applicant tracking systems parse resumes with the help of natural language processing. Then compare the parsed resume data with available job descriptions.

These Artificial Intelligence applicant tracking systems are really good at profiling candidates for skill experience level and how relevant they are, to the job. This basically means that Artificial Intelligence applicant tracking systems can cut the time it takes to hire someone in half.

## Chatbots and Candidate Engagement:

Recruitment chatbots are really helpful. They can respond to questions those seeking work may have. Recruitment chatbots also are able to schedule interviews. Keep job applicants in the loop. That means anyone who isn't coming on for a job can speak with the recruitment chatbots from start to finish. For the people applying, it kneecaps what could be a search for work. Recruitment chatbots assist with that by ensuring people receive everything they need to know about their application.

## Predictive Analytics for Hiring Decisions:

The test of whether somebody is going to do a job or not, we can look at from the past. This can be things such as how they will fit into the company culture or how well they did in their past. Models And we can use models to learn about what will happen in the future. Historical hiring data and indicators of "fit" are really important. Performance metrics are also important. All of these things can help us and that improves our ability to predict when a candidate will be successful in a role. This is what Human Resources professionals use to make their hiring decisions. For this, historical hiring data is pretty useful. Cultural fit signs are helpful as well. Performance metrics are also useful.

## Bias Reduction and Diversity Hiring:

Artificial intelligence solutions are being created to deal with unfairness in hiring. They do this by removing information from job candidates and only looking at their work experience and skills. The thing is these systems can only be good at their job if the information they are trained on is good and fair. Artificial intelligence relies on this information to make decisions so it is very important that the training data, for intelligence is of high quality.

### Employee Retention and Engagement Analysis:

AI reads between the lines of staff survey results, internal communications and employee behavior patterns to look for signs their engagement might be slipping or they may leave the company. HR professionals can then enact interventions to make retention more successful.

AI is a key enabler in energy systems optimization, demand prediction, renewables integration, and sustainability of the energy industry.

### Smart Grid Management:

AI controls the electric flow in smart grids. The electricity flow is followed-up by AI algorithms that inhale and consume energy of end-users, whether condition and supply configuration. Time-varying can enable efficient and stable energy distribution.

### Predictive Maintenance in Power Plants:

AI monitors wear and tear in turbines, generators and transformers as well as helps detect anomalies. Predictive maintenance minimizes scheduled downtime and maximizes asset uptime.

### Energy Demand Forecasting:

Pattern recognition software analyzes the historical patterns of grid use, temperature predictions and market signals to give a near-perfect forecast of future demand. Utilities use that data to more efficiently generate power and to avoid waste.

### Integration of Renewable Energy:

Artificial intelligence is required to anticipate generation and balance loads, because renewable sources, such as solar and wind, are episodic. The AI can also facilitate the resources' dynamic, and help grid operators to balance energy supply and demand.

### Energy Efficient Buildings and Cities:

AI helps optimize power usage in buildings with its grip on smart HVAC systems, automatic lighting, and occupancy monitoring. AI capture insights from data through smart meters, and Internet of Things (IoT) sensors to reduce energy waste and ensure sustainability.

## 1.1.7 AI in Legal Services

Boosting their competitive advantage Lawyers are using AI to reduce costs, improve efficiency and even increase accuracy when it comes to legal work such as legal research, document review and contract analysis.

### Legal Research Automation:

NLP solutions such as ROSS Intelligence and Lexis-Nexis scan the enormous legal databases for these types of case law workflows and are able to extract precedents. This also saves a lot of time when it comes to doing legal research.

#### Contract Analysis and Review:

Artificial intelligence systems are now being deployed to review contracts, in an attempt to flag risks and encourage compliance. These are things you can use to spot anomalies, missing content or a variation from the vernacular legal language – the kind of thing that accelerates due diligence in M&A.

#### E-Discovery and Document Sorting:

In the lawsuit room, AI is helping out with electronic discovery, scanning through a sea of thousands of documents, emails, messages — you name it — to fish out the evidence that matters. These algorithms learn from each case and are always improving over time. Legal Chatbots and Client Services:

Similarly, law firms and legal aid organizations deploy AI chatbots to provide users with answers to simple questions about the law, assist in form completion and point them toward services. They are there to improve access for the public to the law.

#### Predictive Legal Analytics:

Artificial intelligence analyses former case data, judgments and legal argument to determine the outcome of the law process. This enables law firms to determine risk and determine the probabilities of success in litigation.

### 1.1.8 AI in Real Estate

Real estate is being changed by Artificial Intelligence, which is making it easier to manage the value of properties. Artificial Intelligence is helping us to guess what will happen in the market and give customers what they really want. This is a deal, for people who buy and sell properties because Artificial Intelligence is making it easier for them to get the information they need about real estate.

#### Property Valuation and Market Analysis:

AI models look at things like where a property's how big it is what similar properties have sold for in the past and what is happening in the neighborhood. They also look at pictures from satellites. This helps a lot to get an accurate price, for a property and make good investment decisions. AI models use all these things to figure out the value of a property.

#### Buyer-Focused Virtual Assistants and Chatbots:

Real estate websites use intelligence chatbots to answer questions about properties set up visits and recommend listings that fit what the user is looking for. These virtual agents are really helpful. Can even increase the number of people who actually buy or rent properties. They can also reduce the need for human staff to handle the point of contact with customers, which is usually the front end of the business. Real estate websites benefit from using these agents because they can help with tasks such as booking visits and suggesting properties that match the user criteria of real estate

websites.

#### Predictive Modeling for Investment:

Artificial intelligence forecasts what future property values will be and it also looks at income potential and market trends. These forecasts help investors figure out when and where to buy or sell real estate assets so they can do it with confidence. The artificial intelligence gives investors an idea of what to expect from the property values and rental income potential and market trends.

#### Image Recognition in Property Listings:

Artificial intelligence can look at pictures in property listings to find things like what kind of floors they have and how big the rooms are. It can also tell if a place is furnished or not. This is really helpful because it makes searching for a place for the user. The user can actually see what they are looking for and filter properties based on what they want to see. Artificial intelligence makes searching for properties visual, for the user.

#### Fraud Detection in Transactions:

AI systems watch transaction data for signs of money laundering or other illicit behavior, to avoid prosecution under real estate laws governing high-value properties.

### 1.1.9 AI in Defense and Security

In the areas of defense and national security Artificial Intelligence is used for making plans watching and spying protecting against cyber attacks and other things that Artificial Intelligence can do on its own. These things bring up questions about what is right and wrong and how they affect the relationships between countries. Artificial Intelligence is used in ways, in defense and national security and it is important to think about the problems that Artificial Intelligence can cause.

#### Autonomous Weapons and Military Robotics:

Unmanned aerial vehicles, also known as UAVs and ground robots and autonomous naval platforms can go to bad places with very little help from people. These unmanned aerial vehicles and ground robots and autonomous naval platforms are used for things, like looking finding targets and getting supplies from one place to another.

#### Surveillance and Threat Detection:

AI sorts through reams of video, satellite imagery and sensor data to identify anomalies, monitor borders or pick up potential news security threats. Facial recognition and behavioral analysis tools further enhance the situational awareness. Cybersecurity and Information Warfare:

AI can even prevent cyberattacks where you or I couldn't — by spotting malware, finding security holes and reacting to intrusions automatically. A.I. is also being employed in the information warfare to address and fight off disinformation campaigns.

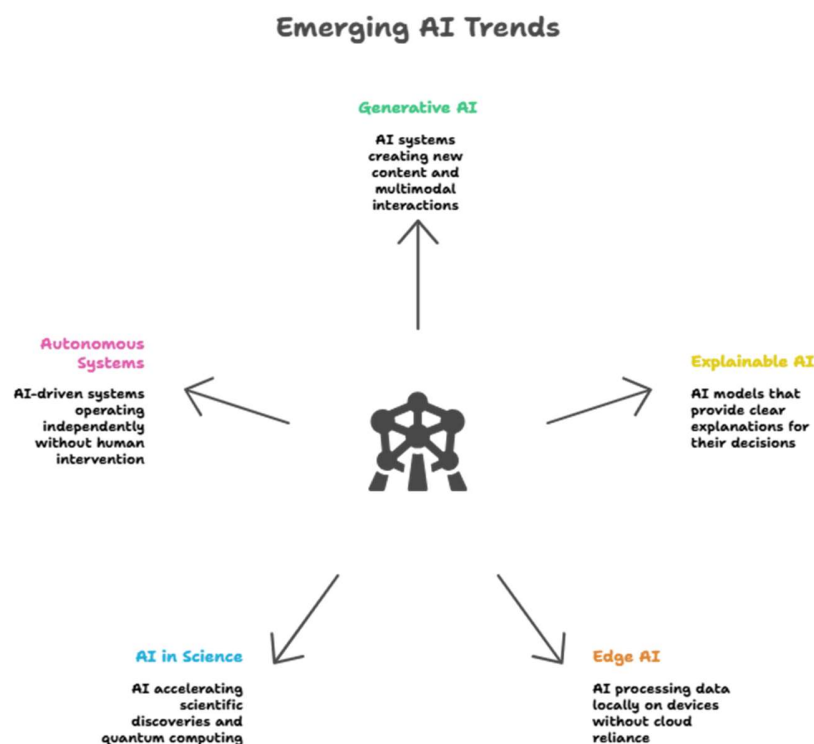

Systems to support command decisions:

Simulation backed by AI and scenario modeling is how military strategists ready missions, judge enemy capacity and resource deployment most efficiently. Such devices are also utilized to integrate battlefield intelligence and tactical information in real-time. Disaster Response and Humanitarian Aid:

Disaster relief The military and security services employ AI to assist coordination after disaster strikes – by analysing satellite imagery, predicting which way a natural disaster might move and optimising the way resources can be deployed.

## 1.2 Future Scope of AI

### 1.2.1 Emerging AI Trends

Several new developments are shaping the direction of AI, altering what machines can learn, perceive and do. Here are the signs that demonstrate how these trends aren't just about AI growing up and moving forward, they're also about AI aligning with other concepts at the cutting edge.

#### a. Generative AI and Multimodal Systems.

Generative AI has been a break-out development, spearheaded by transformer-based architectures. This is changing the way we create things like text and other stuff. For instance we have systems such as GPT that can generate text, DALL·E that can generate images and MusicLM that can generate audio. That demonstrates what the capacity of Artificial Intelligence is to make things that look like people made them. Now we have AI systems that can perceive and integrate info from senses such as vision, hearing and language. This is facilitating conversation with computers and making it more natural to converse. AI can create content like text and images that's just as good, if not better than what people can make.

#### b. XAI - Explainable and Interpretability AI (XAI)

We really need to figure out how these complicated AI models work, the deep neural networks. “We really need to know what those models are doing. Explainable AI is creating models that can tell us how they come to their conclusions. This is one reason we can trust the models. It is also easier to regulate in some industries, such as health care and finance. Explainable AI is also important because it helps us understand the neural networks and other complex AI models.

#### (c) Edge AI and Federated Learning

People need Artificial Intelligence to work fast and keep personal information safe. This is why they want Edge Artificial Intelligence. Edge Artificial Intelligence does the work of Artificial Intelligence outside of the computer systems or the cloud.

This happens at the edge on devices like mobiles, Internet of Things sensors or autonomous cars. Federated Learning helps to keep Artificial Intelligence private by training models that are not controlled by one person over a sample of users while keeping their data safe and limiting who can see it which makes LEARNING work better. Federated Learning makes sure that LEARNING is effective, by doing things this way.

AI is also being used to speed up scientific discovery in areas such as chemistry, biology and climate science. For instance, DeepMind's AlphaFold reimaged protein structure prediction. In addition, The convergence of AI and quantum computing is paving the way to new territories, as with quantum AI algorithms that may be able to solve problems that are impossible for classical computers.e Autonomous Environments and General AI

There is ongoing progress in robotics and Autonomous systems (AS) ranging from real-world navigation, manipulation to multi-agent coordination. Again the decades' long quest for Artificial General Intelligence (AGI) is alive and well, in which to build machines that can learn anything a human knows how to do, in any domain of knowledge.

### 1.2.2 AI and the Future of Work

AI is changing the nature of work – not by replacing people, but by transforming how and where we work. Artificial Intelligence is reshaping the future of work – not by ruling out human labour –but how, where and in collaboration with whom we will be working. The coming decade will be of a generation of human-AI collaboration: hyper-personalised workflows, and work and labour where lifelong learning, ethical governance of technology and adaptability in one's professional career become key.

#### a. Automated Routine Functions

Artificial intelligence (AI) systems are being applied to automate repetitive and rule-based operations across various domains, including manufacturing, finance, logistics and customer service. The very automation raises productivity rate, but at the same time contributes to replacement of low-skill jobs. But rather than cause massive unemployment, automation is placing more of an emphasis on humans to focus on the creative, strategic and relational.

#### b. Emergence of Human–AI Collaboration

Artificial Intelligence is not taking the place of workers.

Artificial Intelligence is actually an important helper.

It assists Artificial Intelligence users with making decisions and being more productive.

Artificial Intelligence also helps people come up with ideas when they are working on something.

Artificial Intelligence is really useful in areas. For example in the field of medicine Artificial Intelligence helps doctors figure out what is wrong with people. It is like a tool that assists them in doing their job

Artificial Intelligence also makes a difference in law. It makes it faster to do research, which's a big part of a lawyers job. This means lawyers can get things done quickly.

In the news industry Artificial Intelligence assists with going through a lot of information. This is very helpful because there is much news to sort through every day. Artificial Intelligence helps make sense of it all which's really important for people who work in news. Artificial Intelligence is very good, at helping people in these jobs.

When people work together with Artificial Intelligence they can give Artificial Intelligence the tasks that need to be done over and over. This way people can focus on the work that needs them to think carefully and be understanding. People have to make decisions and that is something that Artificial Intelligence is not good at.

AI is great at repeating things. That way, people can offload those tasks onto Artificial Intelligence. Then people can use their time to do things that need a touch. This means that people can be kind and make choices. AI is useful, on the boring taking-too-much-time tasks.

#### c. New Job Opportunities and the Skills Needed

Artificial Intelligence has given birth to some types of jobs. Nowadays, we have jobs such as Artificial Intelligence ethicists and those who add comments to data. There are engineers writing code to do machine learning and people auditing algorithms to ensure they are fair.

Then there are designers who make sense of how humans and artificial intelligence might collaborate.

Those Artificial Intelligence jobs require people to be a positive, with technology and knowing how Artificial Intelligence works. Those who use Artificial Intelligence need to understand what it is, and why and how it works.

You want people to have skills, like literacy and creativity. They also need to exercise reasoning and communication abilities. People should be free to vent on their own and reason things through in a sane fashion. Everybody needs to be able to read and write and be creative.

Honestly, between the freelance platforms and the gig economy — things are changing. But that people are using these skills in jobs like reading and writing well or being creative. Freelance platforms and the gig economy are enabling people to use reasoning and communication. People doing freelance work, or in the gig economy, even need to know what's right and wrong and how to have a good conversation with people.

#### d. Skilling, Life Long Learning and Flexibility

We have to change how we learn and how we work, because it's too hectic these days. The world is changing fast: and we need to change with it. We need to figure out how to learn and work anew in this age of astonishment. The advancing age is upon us and we need transform the way get ourselves about if we are to flourish.

Governments, schools and companies are pouring money into programs that teach people to use Artificial Intelligence. They want people to code and study Artificial Intelligence. It's a deal because A.I. is becoming really important." Governments, schools and companies believe that it is worth investing in programmes to educate people about A.I. and computers.

These programs are paying for types of classes. These are science and math classes. They also teach critical thinking and emotional intelligence. The programs are assisting to cover the costs involved in taking classes that do both. These classes really help because they teach kids how to think and they also instruct about emotional intelligence and basic science and math skills.

We have to learn all the time. Learning all the time is necessary for us to keep our jobs in a world that is always changing. We cannot just stop learning because the world is changing fast. Learning all the time is something that we must do to stay ahead and keep working.

Learning is really important. We have to keep doing it so we can do our jobs and make a living. Learning helps us stay in the workforce. The workforce is a place and we need to learn new things to survive in the workforce.

#### e. Workflows that are Remote & Hyper-Personalized

We are going to start seeing Artificial Intelligence enabled solutions that give people personalized work experiences.

These work experiences are defined by the persons working style and the things the person likes to do.

Artificial Intelligence enabled solutions are also based on the persons data and the kind of tasks the person likes to do which is called the persons rhythm.

The persons cognitive rhythm is really important, for Artificial Intelligence enabled solutions to work.

Artificial Intelligence tools are really helping people do their jobs from home or from a combination of home and office. This mix of home and office work became very popular because of the pandemic. Artificial Intelligence tools can manage teams that are spread out in places. They can also set schedules automatically. This makes it easier for people to work together over the internet using Artificial Intelligence tools. Artificial Intelligence tools are very useful, for people who work together as a team.

#### f. Working ethics, trust and governance

AI in hiring, performance reviews and employee home monitoring has its risks around bias, privacy and worker freedom. Explainability, fairness and strong governance frameworks are essential to trust in AI systems. They need to make sure they build ethics into the deployment of AI and have a way for workers to control how machines interact with them

#### .AI and Ethics: Opportunities and Challenges

As artificial intelligence becomes a part of our lives we need to think about what is right and wrong when we make these systems. Artificial intelligence is something that affects us all. We want artificial intelligence to be fair and to be used in a way that's responsible. Artificial intelligence needs to work with the values that are important to people like being fair to everyone and making sure someone is, in charge when things go wrong. Artificial intelligence is a deal and we need to make sure it is used in a good way.

#### a. Bias and Fairness

AI systems often get ideas from the information they learn from. This can cause problems with things like recognizing faces choosing who to hire and deciding who gets credit. These problems show that AI can make unfair things happen in our society. To fix this people have come up with ways to make AI systems fairer like changing the data they learn from adding rules to make them behave and using techniques to find and remove biases, from AI systems that are supposed to be fair.

#### b. Privacy and Surveillance

The use of Artificial Intelligence in collecting and looking at data can cause problems with peoples privacy. Systems that watch people and recognize faces or police programs that try to predict what will happen can be very bad for peoples freedom if nobody is watching to make sure they are used correctly. We need to make Artificial Intelligence that people can trust and that is fair. This means that Artificial Intelligence needs to be made with privacy, in mind from the start. It should not be allowed to collect data without asking people it should only collect the data it really needs and it should be made to be secure so peoples information is safe. Artificial Intelligence systems need to be designed with these rules in mind to make sure they do not hurt peoples privacy.

#### c. Accountability and Transparency

#### d. When Artificial Intelligence systems make life-altering decisions such as giving out loans, diagnosing diseases or making legal judgments it is also necessary to be able hold someone responsible for what Artificial

- e. It is only fair: Artificial Intelligence systems should be transparent so we can see how they work.
- f. We must keep an audit trail of what systems do with Artificial Intelligence. We have to be able to understand the decisions that Artificial Intelligence systems make.
- g. So that if an AI system makes a decision, we can revisit it. Call it wrong if you have to.
- h. a. Autonomy and Man's Dignity
- i. When AI is deployed to make decisions in fields such as medicine or the assistance of people, it is taken into account that people should be treated with respect and dignity. Anything that related to effects on people's feelings or any consequences (like human rights) should always be the domain of humans not machines. That's because those kinds of decisions are highly significant and can affect people's lives. Human rights decisions should never be made by artificial entities, because they're about things that are very close to humans. \
- j. b. weaponisation, and dual use technologies
- k. We have a big problem with intelligence for autonomous weaponry and surveillance. It can be very problematic and risky for everybody."
- l. There are groups discussing ways to control these automated weapons.
- m. They are also grappling with what to do when intelligence can serve both military and ordinary people.
- n. This is because artificial intelligence can be applied in various ways, such as for military applications or for the general public.
- o. A big issue that we need to grapple with is the arms race for artificial intelligence.
- p. f. Regulation and Global Governance
- q. The issue of how to establish AI governance frameworks is being debated not only internationally, in organisations such as the OECD, UNESCO and EU. Key principles are transparency, fairness, safety and robustness as well as human-in-the-loop. Yet a patchwork of regulation and geopolitical rivalry could stifle the emergence of shared ethical norms.

## The Road Ahead for AI Research and Development

AI R&D has now entered a second phase that is characterized not only by ongoing interdisciplinary convergence of multiple scientific areas, but also increasingly by societal engagement and ambition to create human-centered innovation.

### a. Interdisciplinary Integration

The future of AI R&D lies in the intersection of Computer Science, Neuroscience, Psychology as well as Ethics and Law & Social Sciences. If we actually want to create systems that are truly intelligent, then it is critical for us to know how humans think and behave. There is also a push to bring AI into new domains such as materials science, bioinformatics and economics, thus expanding the scope of its research.

### b. Human-Centered AI Design

There is an increasing focus on the design of AI that is compatible with human values, preferences and socio-cultural systems. The focus of Human-centered AI is on usability, fairness, interpretability and inclusion. It fosters cooperation among developers, users and stakeholders to ensure AI serves the public interest."

### c. Advancing Fundamental Research

While a number of impressive purpose-specific domains have been developed, many fundamental problems in AI remain unresolved. Much work is currently underway on:

- Causal Inference: Empower AI to recognise cause and effect (not just correlation).
- Lifelong learning: Constructing models that continue to learn over time without forgetting what they have already learned.
- Commonsense reasoning: Generalizing AI's knowledge and reasoning process to the real world and 日常.
- Robustness and generalization: Making AI systems work well even in new scenarios.

#### d. Open Source and Coordinated Innovation

AI has been driven by open source and global pools of research. CoinCADE: shared datasets, model repositories and joint benchmarks facilitate transparency, reproducibility and progress at speed. OpenAI, Hugging Face and DeepMind are among projects that all talk to the public about AI.

#### e. Scaling with Responsibility

The trend toward scaling AI models — such as the large language models containing billions of parameters — raises fears about computational expense, energy consumption and responsible usage. The research to come will undoubtedly be more empathetic toward green AI, model efficiency, and low-resource learning frameworks that enable individuals who did not previously have access to such tools.

#### f. Public Engagement and Participatory AI

As the reach of AI systems affects larger sections of society, public engagement in conversations about development and use is increasingly necessary. Participatory models of AI enhance transparency and citizen involvement in the development of AI policies, to ensure that technology is developed in line with societal values and interests.

### Knowledge Check 1

Choose the correct option:

1. **Which of the following best defines "Explainable AI (XAI)"?**
  - A. AI that generates creative outputs like music and art
  - B. AI systems that can provide human-like emotional responses
  - C. AI models that allow users to understand and interpret decision-making processes

2. What is one of the key benefits of Federated Learning in AI development?
  - A. It eliminates the need for machine learning models
  - B. It allows AI models to be trained on data without transferring it to a central server
  - C. It reduces the cost of quantum computing
  - D. It enables the use of AI in agriculture only
3. According to emerging trends, how is AI expected to impact the future of work?
  - A. By replacing all human roles across sectors
  - B. By automating creative thinking completely
  - C. By creating hybrid human-AI collaboration teams that augment productivity
  - D. By removing the need for employee training programs
4. What is one of the main ethical challenges associated with AI systems?
  - A. Lack of processing speed
  - B. Biased outcomes due to training data
  - C. Absence of hardware compatibility
  - D. Inability to collect user feedback
5. Which of the following is a current research focus area in AI development?
  - A. Manual data entry techniques
  - B. Increased dependence on centralized computing
  - C. Causal reasoning and continual learning
  - D. Static rule-based systems

## 1.3 AI Applications in Creative, Business & Cross Domains

### 1.3.1 AI in Design and Creative Domains

Advancing creative industries with Artificial Intelligence AI is changing the nature of creativity – and with it a surprising number of industry niches, whether they are art in advertising or visual design. In the space of creativity AI doesn't just serve as an enhancement to automation, but also a co-creator, capable of producing, refining and inspiring new aesthetic expressions and functional arrangements.

**“Activity”**

visuals. Try a text-to-image AI generator such as DALL·E, Bing Image Creator or Craiyon. Provide descriptive cues related to the theme you've chosen and produce a minimum of three AI-generated artworks. Read the outputs to see whether the AI managed to convey visual elements, mood and coherence. Record any surprises or lapses in the way A.I. read abstractions into literal expressions. Send us your three images, along with a short write-up about the nature of the creative input from you, how effectively AI handled it and whether you believe that AI can itself be a collaborator in professional creative work.

#### a. Generative Design and Art Making

AI-based generative design applications rely on optimization algorithms to search a large space of potential designs within given constraints. In architecture and industrial design, platforms such as Autodesk's Generative Design suggest structurally efficient shapes that balance form with real-world performance constraints (such as weight, strength, material cost).

In the realm of urban transport and mobility, it is used to plan road layouts, bike lanes, traffic efficiency optimizations and intelligent infrastructure that changes according to pedestrian behavior, humidity or light levels.

Applications in visual arts, such as Artbreeder, DeepArt and DALL·E, leverage neural networks to create new images or mix different artistic styles or combine both based on textual prompts. These resources enable tooled rapid fire ideation, cross style play and professional empowerment to laymen & professionals!

#### b. Music and Sounds Design

AI solutions including AIVA, Amper Music and Soundraw create unique music designed for a mood, genre or application (e.g., film, gaming or advertising). AIs can mimic the styles of classical composers or it can produce completely novel aural palettes by mining rhythm, timbre, and harmonic structures.

In games or interactive experiences, AI-composed music reacts to the emotions of the player or events in the game, producing an immersive, dynamic soundscape.

#### c. Writing, Storytelling and Literary Arts

NLP models such as GPT-4, Sudowrite and Jasper are now enabling human-AI co-authorship for screenwriting, poetry, journalism and content marketing. These are aids to: the creative process, characterisation, narrative storyworlding and stylistic finesse.

In advertising, AI is being employed to write persuasive copy tailored to different demographics and emotions by maximizing engagement across digital placements.

#### d. Fashion Designing and Aesthetic Prediction

AI models cull through color trends, fabric textures, body measurements and consumer behavior to forecast new styles in fashion. AI-powered platforms are utilized by designers to visualize and test pieces of clothing in virtual fitting rooms or 3D fashion simulations, reducing the time for prototyping a product and minimizing waste of material.

Start-ups are even using A.I. to create ultra-personalized fashion recommendations, instantly shaping styles around individual consumers' particular preferences.

#### e. Transport, Product and UX design

In car design, AI optimizes aerodynamic shapes and ergonomic interiors and user-friendly dash interfaces. For example, even corporations such as BMW and Tesla are employing AI for not only car design but also the human / machine interface (HMI).

Material selection or form factor optimization and sustainability aspects in product design are also supported by AI. Generative algorithms are designing lightweight parts that take off in aerospace and consumer electronics, leading with a more Earth-friendly footprint.

UX/UI design benefits as well, with AI-powered tools that anticipate user behaviors, offer layout refinements and can even construct wireframes based on user goals and usage patterns — all at a faster pace of iteration.

#### f. Philosophical and Ethical Reflections

As AI becomes more involved in creating works of authorship and inventions, the paradoxes of authorship, originality and intellectual property will be heightened. Who gets to own a composition created by an algorithm trained on millions of human works? Can AI art be copyrighted? And how do we properly credit in such co-creative systems? The stakes of the above questions are shot through with larger philosophical issues regarding machines and creativity, the challenge of artistic intentionality, and about where human agency lies in art-making. As AI more and more blurs the concept of tool versus peer, novel legal and cultural schema will replace as possession, liability and ethical usage.

#### AI in Design and Business Domains

Impact: Combining core AI with business/Design Thinking, they create data-drive user-centric innovations that are reshaping decision making, product development and customer engagement. What AI in this environment sits as is becoming a design partner and strategic enabler, spanning industries verticals.

##### a. UI and UX Design

Today, AI is abundantly leveraged for analyzing and improving user interfaces by tracking the behavior of users and then predicting their pattern of use as well as recommending better options. And tools such as Adobe Sensei, for its part, take data on heatmaps, click-throughs and scrolling behavior to help optimize the layout and usability within digital products.

##### b. Charting and Customization of the Customer Journey

Designers and marketers can use AI to create custom-fit customer experiences by building personas and predicting behaviour at digital interaction points. With AI driven A/B testing, user interfaces and messaging can be adapted on-the-fly based on how users respond.

##### c. Creating New Products and Services

It can be used in ideation and prototyping of product development by identifying market trends, analysis of unmet needs and virtual prototyping. Generative AI can now create item roadmaps, a/b test new variations and suggest different layouts with minimal human help.

#### d. Identity Systems and Visual Communication

AI are tools that can assist graphic designers to develop logos, layout and marketing material by reading brand guides and design options. It not only automates design tasks you have to do on a daily basis; it's easy, intuitive use opens up new creative opportunities in visual branding.

#### e. Integrated Strategy and Analytics

AI continues to be integrated further and deeper into strategic design thinking (i.e., it's being used to construct tuned customer personas, read market sentiment and competition play) to outline long-range business planning. Policy makers are also using AI dashboards to visualise complex data and create stories this is like bridging the gap between design and business strategies.

#### f. Learning: DataDriven Creativity and Performance Optimization

“Designing with AI becomes cyclical, as outputs of creativity are experimented with in the world and performance data feeds back into the design process. “That’s a continuous optimization model... Aligning design output to business goals of engagement, retention and conversion.

#### AI in Design and Cross Domains

AI's ability of learning how to adapt and design solutions is fostering inter disciplinary engagements in sciences. Sitting at the nexus of design and technology, AI is providing new ways for us to work together as we pursue answers across a range of scientific, engineering and social disciplines.

##### a. AI in Architecture and Urban Planning

Today, architects employ AI to simulate environmental conditions, enhance structural iterations and analyse urban dynamics. ‘AI based models are applied to measure energy use, crowd dynamics and environmental impact,’ they write ‘to create responsive new sustainable environments.’

##### b. AI in Biomedical and Health What is Design

In biological engineering and health, it's been aiding in amazing 3D design of powerful prosthetic devices and implants, and other medical gear tailored to a patient's anatomy with deep learning. Bioengineers collaborate with designers to improve the ergonomics, functionality and design of healthcaring solutions.

##### c. AI in Environment, Sustainable and Participatory Design

AI also assists environmental designers to simulate and monitor the effect of materials, construction techniques, as well as resource usage. Generative design tools combined with environmental simulations will facilitate low-carbon product and infrastructure design.

Cognitive AI is applied in fields such as behavioral science and human-centered design to create sentient systems that empathize with user emotions, preferences, and decision-making styles. They enhance the design of educational tools, mental health apps and adaptive learning environments.

#### e. Integrative Education and Creative Research

Applications, informed by AI, are at the heart of transdisciplinary curricula that bring together design thinking and AI engineering, data science, and the humanities. Researchers and students investigate speculative design, interactive AI-systems, experimental interfaces that cut across existing disciplinary divisions.

#### f. Design with Ethical and Inclusive Innovation in Mind

Cross-domain AI is more and more driven by the idea of ethical design principles like transparency, inclusivity and cultural appropriateness. Designers who work in multidisciplinary teams have to be careful that new AI solutions respect a wide range of user needs, and that they do not perpetuate societal biases.

## 1.4 Summary

v Artificial Intelligence (AI) is basically a computer (machine) system that can do tasks that human do which need the intelligence = reasoning, learning, problem solving, perception and language understanding.

v The roots of AI can be traced to early philosophical conceptions about logic and reasoning, through the development of electronic computing in the mid-20th century. Milestones include the Turing Test, Dartmouth Conference (1956), and several AI "winters" over obstacles in technology.

v Contemporary AI includes areas such as Machine Learning (ML), Natural Language Processing (NLP), Computer Vision, Robotics and Expert Systems with fundamental aspects of learning, reasoning, perception and action.

v AI is getting implemented across a variety of industries for innovation and enhanced efficiency.

v In the field of healthcare, AI is applied to diagnostics, predictive analytics preventive medicine as well as drug discovery and virtual health assistant.

v Applications in finance include fraud detection and algorithmic trading, credit scoring, as well as chatbots powered by AI.

v AI in education through adaptive learning, intelligent tutoring systems and prediction of student performance.

v In manufacturing and retail, AI enables predictive maintenance, quality control, customer behavior prediction and warehouse automation.

v Smart cities and transportation AI is also being used in technology applications for smart cities and transportation for autonomous cars, traffic management, public surveillance and infrastructure monitoring.

v E-commerce harnesses AI for product recommendations, dynamic pricing, customer service automation and fraud

- v Social media relies on AI for content personalization, sentiment analysis, and content moderation.
- v Within telecommunications, AI benefits network optimization, predictive maintenance, and natural language-driven services.
- v AI is changing industries from travel to augmented reality, autonomous vehicles and drones.
- v The next frontier of AI consists of emerging trends such as generative AI, edge computing, explainable AI and AI-quantum computing integration.
- v The relationship between AI and the future of work is about job transformation, augmentation and human-AI collaboration.
- v Ethics involves bias, fairness, transparency, privacy, surveillance and regulation of autonomous systems.
- v Advances in AI research are being made through interdisciplinary, participatory, human-centered and sustainable innovation.
- v Here are our picks: Creative and cross-domain uses of AI — from art to privacy Fashion world fawns over suggestive\$ \_2 technology Polestar 2 is the first car with built-in Google \_\_computing Game over for HQ Trivia?

## 1.5 Key Terms

Artificial Intelligence (AI):

Machines, especially computer systems, having a human-like capacity for thought.

Machine Learning (ML):

A field of AI that allows systems to learn from data rather than being explicitly programmed.

Natural Language Processing (NLP):

The AI power to comprehend, interpret and generate human language.

Generative AI:

AI models that generate new content, like text, images or music, based on patterns they've learned.

Explainable AI (XAI):

AI systems that are rationally explicable in the way they reach decisions.

Predictive Analytics:

Prediction of the future based on historical data using AI for data analysis.

Human-Centered Design:

The process of developing AI systems with respect to user perspective, ethics, and usability.

Edge AI:

AI processing performed directly on devices rather than in centralized cloud systems, a speed-up that can also protect privacy.

## 1.6 Descriptive Questions

What are the primary attributes of an AI system?

How has the history of AI driven recent technological innovation?

How is AI changing healthcare?

Describe the role of AI in financial fraud detection and credit rating.

How AI enables personalized learning in education: Explain.

How is the ethical aspect about AI and decision-making?

What is the difference between generative AI and a traditional (rule-based) system?

Explain the importance of human-centric design with respect to AI applications across domains.

### Answers to Knowledge Check

#### *Knowledge Check 1*

1. C
2. B.

3. C. By creating hybrid human-AI collaboration teams that augment productivity
4. B. Biased outcomes due to training data
5. C. Causal reasoning and continual learning

## 1.8 Case Study

### Strategic Integration of AI Across Sectors to Drive Innovation and Efficiency

#### Introduction

As Artificial Intelligence (AI) continues to redefine industries, the integration of AI across creative, business, and technical domains has become crucial for organizations seeking sustained innovation. From automating complex processes to augmenting human decision-making, AI's transformative impact is visible across sectors such as healthcare, education, finance, design, and beyond. This case study examines how organizations are leveraging AI capabilities to enhance productivity, drive personalization, and solve sector-specific challenges.

#### Background

The 21st century has witnessed AI evolve from a theoretical concept into an applied technology reshaping global industries. Key developments like deep learning, generative models, and natural language processing have enabled AI to move beyond data automation into cognition, prediction, and creativity. While its applications differ by sector, the core capabilities of AI—learning, problem-solving, reasoning, and perception—are universally relevant. Despite its promise, challenges such as ethical concerns, skill gaps, and integration complexities persist.

#### Problem 1: Fragmented Adoption Across Industries

Although AI tools are available, many industries have adopted them unevenly. In sectors like education and agriculture, implementation lags due to infrastructure limitations, lack of awareness, or resistance to technological change. As a result, institutions miss opportunities to personalize learning, improve productivity, or optimize resource use.

#### Solution:

Governments and industry leaders have initiated capacity-building programs to promote AI literacy, incentivize research, and create sector-specific frameworks. For example, AI-based adaptive learning platforms are now increasingly integrated in schools to support personalized education, and precision agriculture solutions are being subsidized to support rural innovation.

The deployment of AI in legal services, HR, and defense raises critical ethical concerns related to data privacy, bias, surveillance, and autonomous decision-making. Without clear policies, these systems can produce discriminatory outcomes or compromise human rights.

#### Solution:

Interdisciplinary AI governance frameworks have been introduced by bodies such as the OECD and EU to enforce transparency, fairness, and accountability. AI tools in HR now include fairness audits, while military AI operates under human-in-the-loop protocols to ensure oversight.

### Problem 3: Creative and Cross-Domain Integration Barriers

While AI has been adopted in design, media, and entertainment, some creatives view it as a threat rather than a tool. There's also a knowledge gap in how to apply AI collaboratively across design, business, and technology functions.

#### Solution:

Design schools and creative industries have started including AI literacy and co-creation tools like generative art software in their curricula. Businesses use AI-enabled UX design tools and predictive analytics to merge design thinking with strategic decision-making.

### Reflective Questions

- How can interdisciplinary AI education improve adoption across traditional and emerging sectors?
- What policies are essential to ensure AI aligns with ethical standards in sensitive industries?

How should industries balance human creativity with AI-generated design outputs?

**Download Date**

Feb 5, 2026, 11:02 AM GMT+5:30

**File Name**

FFAI\_Unit 2.docx

**File Size**

217.0 KB

**30 Pages**

**7,266 Words**

**42,738 Characters**

## \*% detected as AI

AI detection includes the possibility of false positives. Although some text in this submission is likely AI generated, scores below the 20% threshold are not surfaced because they have a higher likelihood of false positives.

### Caution: Review required.

It is essential to understand the limitations of AI detection before making decisions about a student's work. We encourage you to learn more about Turnitin's AI detection capabilities before using the tool.

### Disclaimer

Our AI writing assessment is designed to help educators identify text that might be prepared by a generative AI tool. Our AI writing assessment may not always be accurate (i.e., our AI models may produce either false positive results or false negative results), so it should not be used as the sole basis for adverse actions against a student. It takes further scrutiny and human judgment in conjunction with an organization's application of its specific academic policies to determine whether any academic misconduct has occurred.

## Frequently Asked Questions

### How should I interpret Turnitin's AI writing percentage and false positives?

The percentage shown in the AI writing report is the amount of qualifying text within the submission that Turnitin's AI writing detection model determines was either likely AI-generated text from a large-language model or likely AI-generated text that was likely revised using an AI paraphrase tool or word spinner.

False positives (incorrectly flagging human-written text as AI-generated) are a possibility in AI models.

AI detection scores under 20%, which we do not surface in new reports, have a higher likelihood of false positives. To reduce the likelihood of misinterpretation, no score or highlights are attributed and are indicated with an asterisk in the report (\*%).

The AI writing percentage should not be the sole basis to determine whether misconduct has occurred. The reviewer/instructor should use the percentage as a means to start a formative conversation with their student and/or use it to examine the submitted assignment in accordance with their school's policies.

### What does 'qualifying text' mean?

Our model only processes qualifying text in the form of long-form writing. Long-form writing means individual sentences contained in paragraphs that make up a longer piece of written work, such as an essay, a dissertation, or an article, etc. Qualifying text that has been determined to be likely AI-generated will be highlighted in cyan in the submission, and likely AI-generated and then likely AI-paraphrased will be highlighted purple.

Non-qualifying text, such as bullet points, annotated bibliographies, etc., will not be processed and can create disparity between the submission highlights and the percentage shown.

## Unit 2: Foundations and Applications of AI

### Learning Objectives:

1. Categorize the types of AI and differentiate between narrow, general, and superintelligent systems.
2. Describe the basics of Generative AI, and explore the architecture and capabilities of Large Language Models (LLMs).
3. Find and assess some of the LLM's core tools like ChatGPT, Claude ect. in the wild!
4. Explain prompts in the environment of Generative AI and describe different types of prompts
5. Use prompt engineering methodology (skills, notations) to develop and validate AI prompts for enhanced output quality.
6. Discover and fix common errors in prompt writing through experimental recursion.

### Content

## 2.0 Introductory Caselet

### When Words Shape Results — Meera at BrandMuse Digital

Meera- media and communications graduate, was also another of the recent recruits, employed by BrandMuse Digital – a boutique creative agency growing lifestyle brands with content. Facing tight deadlines and demanding clients, the team had already begun to experiment with generative A.I. tools like ChatGPT, Midjourney and Copy. ai to help with content, images and even campaign ideas.

For her first solo assignment, Meera had to come up with a tagline and short social ad copy for an eco- friendly skincare brand. She pulled up her favorite AI tool and wrote:

“Provide a tagline for a botanically-based skincare brand.”

The results were... underwhelming. Generic slogans such as “Glow Naturally” and “Skincare You Can Trust” failed to impress her creative director.

Frustrated, Meera started experimenting. She rephrased her prompt to:

“Write a 5-word tagline for a high-end, environmentally conscious skincare brand for Gen Z that champions clean beauty.”

Suddenly, the findings became crisper and clearer. She narrowed down a few and then, with minimal tweaks, delivered them. Her creative director was impressed: “You cracked the brief— and you made the AI sound like us.

Curious, Meera spent the weekend digging into prompt engineering techniques and updates on prompt types, input structure and finally understanding how do large language models even work. She learned that when you talk to AI, it’s not about what you ask but how you ask. The clearer and more contextualized her prompts, the better it worked. Before long, she emerged as the resident expert on writing AI prompts across the team — from ad copy to image generation to concept decks. A frustration became a superpower.

Critical Thinking Question:

If you are Meera, how would you explain the benefits of learning prompt engineering to a teammate who believes that AI tools should just work and doesn’t need much input?

## 2.1 Types of AI, Generative AI, and Large Language Models (LLMs)

Artificial Intelligence (AI) continues advancing in stride with the myriad systems of all sectors. From automation and analytics to creativity and conversation, it is not an overstatement to say that AI exists in the tools we use every day. Developing an understanding of the new world necessitates a closer look at what types of AI are emerging, how generative AI models have come into prominence, and the promise and peril of Large Language Models (LLMs). Those parts are the cornerstones and/or newest advances in the arena of AI.

### 2.0.1 Types of AI

AIs may be distinguished on multiple grounds according to level of ability, functional behaviour and context of use. Learning about these classifications gives a holistic understanding of what AI systems do and how they are built or used.

#### Based on Capabilities

AI Systems can broadly be categorized into three based on their general capability to carry out tasks and the extent of cognitive imitation of human intelligence:

##### a. Narrow AI (Weak AI):

Narrow AI is AI that is specifically trained and tuned for a specific task. These are machines which function with limited set of parameters and they cannot do any job other than what it was designed to. Most of the AI in circulation today - think spam filters, voice recognition, recommendation engines - fits that bill. They might seem smart but are without consciousness or comprehension.

##### b. General AI (Strong AI):

AGI is any system which can understand, learn and apply intelligence to any problem, in the way that a person can. Such systems could learn from one domain or task, and generalize seamlessly to a new environment. In AI research, productive general AI (the goal of which is the creation of "intelligent agents") is a generational focus among researchers.

##### c. Superintelligent AI:

It's an imagined type of AI that outperforms human intelligence at everything — logic, creativity, emotional intelligence, and social skills. It's often talked about in philosophical, ethical and future tense. Control, value alignment, and existential risks are also big topics of discussion about superintelligent AI.

#### Based on Functionalities

Another helpful way to categorize AI is by how it works -- how it processes data, makes decisions and learns from the environment:

##### a. Reactive Machines:

These are systems that can react to the present, but don't have memory or learn from the past. One classic example

IBM's chess-playing computer, Deep Blue. It could evaluate a game in progress, but it had no memory of past games.

b. Limited Memory:

It is the most common form of AI in use today. Limited memory A.I. can consider past data to make judgments — but then it discards that data soon after. Self-driving automobiles are a prime example, since they rely on constantly updating information about traffic and road conditions to drive themselves.

c. Theory of Mind (theoretical):

I mean A.I. systems that would get what human emotions, beliefs and intentions were. It is still work in progress in the fields of research, e.g., affective computing and human-computer interaction.

d. Self-Aware AI (hypothetical):

This advanced form of AI would have its own consciousness, self-awareness, and the ability to perceive internal states. Self-aware AI is currently just a concept and doesn't exist.

## Based on Application Domains

That classification system defines three "categories" of output based on how the AI interacts with the world:

- Perceptual AI: An AI that senses and understands the world, like image recognition or systems for recognizing speech.

Cognitive AI: It includes cognitive or learning tasks such as decision making, planning and problem solving.

- Autonomous AI: This concept captures systems that can operate independently in complex environments, for instance autonomous drones or robots.

These kinds of AI that are classified according to their strengths and functions, form a basic vocabulary for understanding the entire spectrum of intelligent machines, from very narrow tools to hypothetical, general purpose thinking machines.

### 2.1.1 Generative AI Models

Generative AI is one of the most impressive advancements in artificial intelligence technology. While traditional AI models are used for classification or prediction, generative AI models can produce entirely new content — whether that's text, images, code, music and beyond—based on patterns it learned from.

large datasets. These models are not just copy and pasting information that already exists out there, but they also produce novel and very often highly-realistic outputs.

## Definition and Purpose

Generative AI is a form of machine learning model that can produce original content by learning from data distributions. Such models learn statistical patterns and structures from the input data, which they exploit to generate new samples that resemble the original thermoelasticity2t dataset. This ability empowers generative AI to help or even collaborate with humans in many domains, including design, writing, gaming and filmmaking.

### 8.1 Key Generative AI Models

Among these are a number of model architectures that power generative AI. All of these have their own techniques, advantages and areas of application:

#### a. GANs (Generative Adversarial Networks):

Introduced by Ian Goodfellow in 2014, GANs are a pair of neural networks, financial services companies california the generator and the discriminator, trained at the same time. The generator creates fake data (e.g., images), whereas the discriminator decides if the data is real (from the dataset) or generated. With time, the generator becomes better at generating data that is indistinguishable from real data. GANs have been popularly applied in image generation, fashion and art creation.

#### b. Variational Autoencoders (VAEs):

VAEs are also common generative model architecture. They learn to encode input data into the latent space (compressed form), and then decode the data back from this encoding, using it to reconstruct or generate new data. A trilogy of use-cases for VAEs are human face generation, molecular structures in drug discovery and 3D object generation.

#### c. Transformer-Based Models:

Generative AI has been revolutionized by transformers, particularly in the realm of natural language processing. These models like GPT (Generative Pretrained Transformer), BERT, T5 all heavily depend on attention mechanism for context based understanding and coherence in text generation. Transformers' ability to process sequences is particularly well suited for content generation tasks such as essays, code, poems and summaries.

## 1.4.2 Applications of Generative AI

Generative AI has come a long way including in music generation: machines can generate human-competitive melodies, beats and much more (even if not always on demand due to complexity of the model or training time). These solutions are changing the ways design, entertainment, education, software and product development, medical research and businesses work by accelerating real time interaction with content in turn creating a more engaging user experience.

#### a. Text Generation and Dialogue Systems

Natural language generation (NLG) is one of the most advanced applications of generative AI. AI writing aids like ChatGPT, Jasper and Copy.ai are for automating content writing in blogging, marketing and education. These models can produce essays, reports, scripts and interactive stories. Meanwhile, conversational agents like Google Bard, Meta's BlenderBot and Character.AI generate natural-sounding dialogue for customer service, tutoring, and entertainment: match the user's tone and style.

Illustrative Examples outputs generated by DALL·E, MidJourney and Stable Diffusion can create realistic or non-realistic images with styles from Natural Language prompts. They are used in advertising, concept design, architecture and virtual environments. AI-based image editors such as Adobe Firefly and Runway ML also expedite creative workflows with functions such as inpainting, style transfer or background swapping.

### c. Composition and Sound Synthesis

In music and audio, generative A.I. includes things like OpenAI's Jukebox, AIVA by Polygoniq and Suno.ai, both of which generate original tracks in various styles and tempos. AI models also help with sound design, mood mapping, and even voice synthesis. Techs like ElevenLabs and Descript Overdub are highly authentic text-to-speech and voice cloning tools that add a layer of personalization to audio storytelling for creators.

### Language for Code Generation and Program Implementation

Program synthesis is being transformed by generative AI through technologies such as GitHub Copilot (powered by the OpenAI Codex) and CodeWhisperer from Amazon and Ghostwriter from Replit. It can also autocomplete code, suggest bug fixes and even explain complex algorithms. They are an especially good fit for the commonplace and cut down development time dramatically, opening up coding to non-programmers.

### Video Generation and 3D Content Creation

Recent work on generative video editing applications like Runway Gen-2, Pika and Synthesia can create animated or synthetic videos from text descriptions or static images. In 3D design, tools like Point-E, Kaedim and Spline AI help designers to make assets for games, virtual reality or product-design. These technologies can help to greatly decrease the time and level of expertise required for 3D contents of a higher standard.

### Synthetic Data and Discovery

In the development of machine learning, generative models are being used more and more for synthetic generation—essential when you have issues with privacy, not enough data or to circumvent bias. Platforms like Gretel. It also mentions that ai and Mostly AI generate synthetic data sets that closely resemble real patterns. In scientific domains, generative models are used for drug discovery (e.g., Insilico Medicine), protein folding (e.g., AlphaFold) and materials science by accelerating experimentation and innovation.

### Lifestyle, Gaming and Personalized Content

In the fashion and design industries, generative AI tools like Cala and The Fabricant are helping brands predict trends, model clothes and simulate virtual apparel. And when it comes to gaming specifically, platforms such as Promethean AI and Scenario. gg assist create resources, stories and worlds. And in both education and marketing, AI is leveraged to tailor content — which can be anything from quizzes and study plans to email campaigns and ad creatives — by individual user behavior and preferences.

## Limitations and Challenges

Generative AI, though strong, also comes with a few limitations:

- **Bias Propagation:** When training data contains biases, produced outputs may simply reinforce (or even magnify) the same biases.

- Misinformation/Deepfakes: Generative methods can also generate disinformation and create false reports, which comes with further ethical and social implications.
- Resource Intensity: Training generative models is computationally intensive and can only be done with huge amounts of computational resources and data.

**Ownership and Intellectual Property:** Determining the authorship of AI-generated works is a complicated issue from both legal and ethical standpoint.

### 2.0.1 LLM Models and Tools

Large Language Models (LLMs) are one of the most remarkable developments in AI and NLP. They have revolutionised machine processing of human language, and it would be impossible to generate text or perform translation, summarisation, coding or question answering without them. They are based on the backbone of generative AI systems called LLMs, which can generate human-like text with naturalness and fluency.

This article covers the motivation, definition, architecture, state-of-the-art models and applications presentation of LLMs as well as tools and challenges followed by discussing a comparison between on-line and off-line LLMs along with their use-cases.

## 1. What is a Large Language Model (LLM)?

A LLM is a particular kind of deep learning model which is trained on a massive amount of Data labelled as text from Books, Articles, Websites and so forth. They leverage transformer architectures with billions or trillions of parameters (Vaswani et al., 2017) and are able to learn and produce well-formed language by pretraining and finetuning.

In contrast to previous NLP models that required task-specific architectures, LLMs are general-purpose and can be applied to many different tasks with prompt-based input.

### Core Architecture: The Transformer

The most LLMs are based on the transformer architecture presented in the seminal paper (Vaswani et al., 2017) “Attention is All You Need.” The transformer is designed to efficiently process sequences inputs using self-attention mechanisms while being able to capture longer-distance dependencies.

### Key Components:

- Self-Attention: Measures the importance of each word with respect to others.
- Positional Encoding: This encodes the word order for sequence understanding.
- Encoder/Decoder: Various models have encoders (like BERT), decoders (like GPT) or both (such as T5).

## 2. Prominent LLMs and Their Characteristics

Model

Developer

Architecture

Key Features

GPT (1–4)

OpenAI

Decoder-only

Autoregressive generation, multitask capabilities

BERT

Google

Encoder-only

Bidirectional attention, strong comprehension

T5

Google

Encoder-Decoder

Text-to-text unification of NLP tasks

PaLM

Google

Transformer

Massive scale (540B), multilingual capabilities

LLaMA (1–2)

Meta

Decoder-only

Open-source, efficient for fine-tuning

Claude

Anthropic

Transformer

Emphasize safety and alignment (Constitutional AI)

Gemini

Google DeepMind

Multimodal

Integrates text, image, code capabilities

Applications of LLMs

a. Text-Based Tasks

SUM, GEN, LABA, GC: Summarization, generation, sentiment analysis grammar correction

b. Conversational AI

- Chatbots (ChatGPT, Bard), mental health aides

c. Code Generation

- GitHub Copilot, OpenAI Codex

d. Education & Training

- One-on-one tutoring; computer-generating feedback

e. Search & Retrieval

- Semantic research, domain-specific Q& A

f. Translation

- Google Translate, DeepL, multilingual content creation

### 3. Tools and Platforms for LLM Development and Deployment

Tool / Platform	Function
Hugging Face	Open-source pre-trained models and APIs

<b>OpenAI API</b>	GPT-3, GPT-4, DALL·E, ChatGPT access
<b>Google Vertex AI</b>	Access to PaLM, integration with Google Workspace
<b>Claude API</b>	Aligned LLMs with safer outputs
<b>LangChain</b>	Framework for LLM app development
<b>Azure OpenAI</b>	GPT-powered apps with Microsoft compliance
<b>Fine-Tuning Tools</b>	LoRA, PEFT, QLoRA for efficient customization

**a. Challenges and Limitations of LLMs**

- Hallucination: producing wrong information, or information that is invented or fabricated
- Bias & Fairness: The prediction may be biased by the societal prejudice
- Interpretability: Explanation of LLMs Models developed by LLMs are usually uninterpretable and fine-tuned to the training data at hand.
- Sustainable Design Process, cost 45-48% more in energy and resources than the standard design instead of 18%-22% better[6]
- Security and Misuse: Threat to produce abusive information

Privacy: Risk of training data leakage

**Online vs Offline LLMs**

One of the most significant differences in LLMs is whether they work on cloud (online) or local (offline/on-device). This has implications for data privacy, latency, cost and availability.

**a. Online LLMs (Cloud-Based)**

Online models are hosted and deployed on servers, accessible through its APIs. They tend to enjoy frequent updates, scalability, and better model sizes but they are dependent on internet.

Examples:

- ChatGPT (OpenAI through web/app)
- Claude (Anthropic API)
- Bard/Gemini (Google)

- Azure OpenAI Service (Enterprise-grade GPT) Did not have a presence at the Ignite conference and was mentioned as part of a Group Talk process.

- Perplexity AI (LLM-based search)

Use Cases:

- Enterprise Applications Scalable
- Real-time chatbot integrations
- Customer service and research
- Assistant from any device

## b. Offline LLMs (Local Deployment / On-Device)

Offline models download and execute on device, providing the maximum privacy but having smaller model size to fit to hardware limitations.

Examples:

- LLaMA 2 (Meta – portable)
- Mistral 7B (Open weight, productive for the edge)
- GPT4All (GPT-based models locally hosted)

(MNL) · Alpaca / Vicuna / Orca (Fine-tuned LLaMA flavors)

- PrivateGPT (Offline Q&A on your local documents)
- LLM Studio (by Hugging Face) for local model exploration

Use Cases:

- Privacy sensitive domain (e.g., healthcare, law)
- AI inherent in mobile apps or edge devices
- Remote/low bandwidth areas
- Academic research beyond the Internet

Future Directions and Research Trends

- Multimodal Models — ones that layer texts, images, audio, and video together.
- Efficiency : Quantization, Sparsity, Model Compression
- Open-Source Growth: Democratizing AI with community contributions

### Did You Know?

“Economist. Some advanced LLMs can even do few-shot learning, where they successfully complete a new task after just a couple of examples—without requiring fresh, costly, and time-consuming task-specific retraining”.

Activity :

Select any two different LLMs such as OpenAI’s GPT-3.5, and Google’s PaLM use Bard and provide both with the same prompt. The task may be the following: “Write under 100 words key causes of climate for 10th-grade student”. and compare the results on the following criteria: 1. Accuracy of content 2. Readability and clearness for the core audience 3. Tone and style of writing. Compose 200-250 words to justify which model you find better and why there were differences in their responses, considering the architecture of the model, or training data:

## 2.2 Prompt Engineering

Just-in-time engineering is a crucial premise to make generative AI systems (esp., large language models or LLMs) useful. Because the quality of AI-generated output from these models is based on user inputs - known as prompts - users need to carefully craft their prompt's structure, clarity and intent for desired results. Quick engineering has become more than a simple form of interaction, it is now a unique skill with ramifications for how AI will contribute to research, content creation software development, education and many more sectors.

Prompt engineering is more than asking questions; it's the practice of deliberately engineering prompts to direct the model, constrain the format of its response, or even simulate complex tasks like multi-step reasoning or dialogue or translation. With the increasing sophistication of AI models and diversity of tasks that they can tackle, prompt engineering has emerged as a critical subfield within the AI ecosystem.

### 2.2.1 What is a Prompt?

In generative AI and LLMs, a prompt is the input text that prescribes what the model should generate as output (or, in combination with other data or stimuli). Please note that the prompt is where the conditions and task are set for the model. It can be anything from a solo word to an intricate multilayered direction or even a fake conversation.

Basic Definition:

A prompt is the user query or command which guides the AI model on what to generate, predict, answer, or do.

Examples of Prompts:

· Simple Prompt:

“Translate this into French: Hello, how are you?”

· Instructional Prompt:

“Write a precis in 100 words on the following article.”

· Creative Prompt:

“Write a poem about the sea inspired by Shakespeare.”

· Programming Prompt:

“Create a function that finds the factorial of a number.”

Prompts enable the human operator to communicate to the AI system. Prompts that are clear and straightforward will have the best likelihood of producing a clear and useful response. Bad prompts can yield irrelevant, ambiguous or even false outputs.

## 2.2.2 Role of Prompts in Generative AI

Prompts in generative AI systems — and especially LLMs, such as GPT, Claude or Gemini — are not simply passive calls; instead they represent the means by which users guide, condition and control how the model chooses to perform. The nature of prompts can be considered in different ways:

### Task Specification

Prompts describe the job that AI is being asked to do. For example, the model can write an essay, summarize a news article or generate code — all dependent strictly on the prompt. Unless it's embedded in the prompt, the AI model does not "know" what you're trying to do here.

### Context and Conditioning

Prompts can act as context cues that guide the model to better understand open-ended directions. This in turn also involves incorporating context, such as examples, documents, or previous dialogues history to assist with appropriate response production by the model.

### Format Control

Prompts can specify the structure (or type) of the response, for example bullet point lists, numbered lists, paragraphs, JSON and so on. This can be handy in professional or educational work that requires formatting.

If the prompt is worded in just the right way, users can use it to fake different kinds of voice or characters for the AI. For example, if the model is forced to generate "You are a history professor. Explain to a high school student why there was a World War I" doesn't make this the best answer, shaping style, tone and depth of subject matter.

**Iterative Refinement**

More advanced prompt engineering is the practice of iterative prompting (ie updating or refining input based on model outputs). This allows to increase precision and importance in highly dynamic tasks, as reasoning, problem solving or coding.

**Few-shot and Zero-shot Learning**

Zero-shot prompting is asking a model to produce some output without being shown any examples.

Few-shot prompting gives the model examples within the prompt of how to complete the task.

These methods illustrate that prompts represent input and behavioral guidance to generative models, which has a direct influence on them.

**Did You Know?**

"In some AI systems we fine-tune rather than train a complete model from scratch. Instead of finetuning parameters on a model, developers "train" a fixed prompt embedding which is faster, has better sample efficiency and in our experiments fixes LLM as it often works best."

**2.2.3 Types of Prompts (Instruction, Contextual, Conversational)**

The different types of prompts clarify how to design inputs that are customized for particular use cases. The design of prompt structure depends on the task, user's intent and format of output required

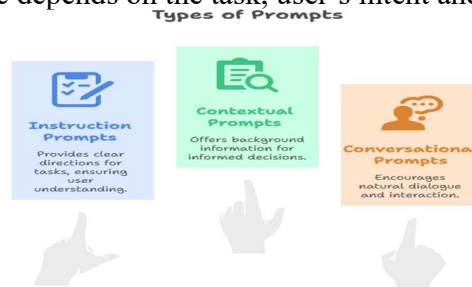

Figure: Types of Prompts (Instruction, Contextual, Conversational)

**1. Instructional Prompts**

These are prompts which explicitly set the AI a task. They typically are starting with running a verb, such as "write", "explain", "sumarize", "translate" or "create".

- “Narrate this paragraph in 100 words.”
- “Implement a Python function that returns a purpose sorted in ascending order.”

Use Cases:

- Summarization
- Translation
- Programming
- Report generation
- Email writing

Benefits:

- Clarity of task
- Controlling output format is very easy
- Automation and productivity friendly

## 2. Contextual Prompts

These prompts are more context, more examples or even reference text that allows the model to better get what the user wants. Context prompts are particularly crucial for few-shot learning or complex, domain-specific tasks.

Example:

- “The first is professional bios. Now, write one like that for this person.”
- “Based on the following conversation history, what to say next: [some dialog].”

Use Cases:

- Create tone/style (custom made)
- Domain-relevant (e.g., medical, legal, technical) content
- Fill in the blank with the context
- Fiction writing and narrative continuity

Benefits:

- More natural sounding outputs

- Reuses system context across transactions
- Tone and relevance improvements

### 3. Conversational Prompts

Prompting refers to input patterns that are used to establish and carry out turn-based interactions between a user and an LLM. This subset of prompts are meant to mimic a conversation where the AI has to

store and reply to history of previous turns in conversation in a contextually relevant manner. Conversational prompts are different from single-turn prompts as they should not only condition on past input, but also continue the line of dialog, track users' intent in a session and respond to them along the way.

**Conversation Prompting Discussion** This section presents an overview of conversational prompting, its use cases, benefits and illustrative examples with explanations.

#### Use Cases of Conversational Prompting

**Customer Service:** Chatbots can help users get to the bottom of product issues, walk them through technical troubleshooting steps or answer common questions.

**Chat-Based Learning:** AI tutor can explain some things, quiz understanding and adjust pace of instruction based on student answers.

**Personal AI Assistants:** Chatbots, and conversational interfaces help to book appointments, answer questions, remind people about stuff and other forms of task automation.

**Real-Time Simulation and Training:** Applied in soft-skill training, therapy simulations or role-play scenarios for users to be prepared for real life contacts.

#### Benefits of Conversational Prompts

1. **Natural Interaction:** These prompts allow the AI to communicate in a human-like way, supporting natural dialogue flow.
2. **Context Retention:** The AI can refer back to earlier parts of the conversation, enabling follow-up questions and clarification.
3. **Dynamic Querying:** Users can explore topics incrementally, receive personalized responses, and shift topics without restarting the interaction.

## Examples of Conversational Prompting with Explanation

### Example 1: Educational Tutor

User: Give the difference between supervised and unsupervised learning?

AI: Supervised learning is learning from a labeled dataset, which means that we have the desired output for each input.

Unsupervised learning unlike the supervised learning doesn't have labelled outputs and it tries to learn based on the structure or pattern in the data.

User: Please could you provide me with one example of each?

AI: Certainly. Spam detection in an email system mimics the setting of supervised learning, for instance, where emails are used to classify spam versus normal (not

spammed or hammed) by a person. In unsupervised learning, an example is marketing customer segmentation, where the task is to discover some groups of customers (clusters) using purchasing behavior but without labels.

Explanation:

The AI keeps the context of the last turn and adds to it. The second reply requires the first as input and offers appropriate examples from real world, hence justifying that the system is capable of context-based reasoning.

Example 2: Customer Support Chatbot User: I want to reset my password.

AI: Are you wanting to reset the password for our mobile app or our website?

User: The website.

AI: You'll want to start at the login page and click on "Forgot Password." You will soon receive an email with a direct link to your profile, where you can update your preferences. If you do not receive this email, please contact us. Do you want me to send that email again?

Explanation:

The AI gets helpful context (what platform we're on) before giving the answer, which would indicate good clarification behavior. It then moves on to follow-up help.

### Example 3: Healthcare Assistant

User: My head has been aching since this morning. What should I do?

A.I.: I'm not a licensed medical professional, but I can provide some general direction. Do you have any other symptoms (nausea, fever, blurry vision)?

User: I feel slightly nauseous.

AI: Based on your symptoms, it is recommended that you are evaluated by a medical provider. Would you like me to look up the closest clinic for you or schedule a telehealth appointment?

Explanation:

The AI hedges its response and without the supporting assertion, and requests additional information to make context-sensitive recommendations. It demonstrates responsible dissemination of sensitive information and escalation to professional assistance.

Example 4: Programming Assistant User: How to reverse a string in Python?

AI: You can reverse a string by slicing it `my_list[::-1]`.

User: I can define a function for that?

AI: Yes. Here's a function:

```
def reverse_string(s): return s[::-1]
```

You can use it like this: `reverse_string("hello")` that will return "olleh".

Explanation:

Not only does the AI give a straight answer, it also responds to the user's subsequent prompt to offer up and expand on that original idea with some useable code.

### Example 5: Personal Assistant Scenario

User: Can you give me a reminder to call my dentist at 3 p.m. tomorrow?

AI: I've set a reminder for 3 p.m. tomorrow. Do you want to put the dentist's number in the reminder?

User: Yes, please.

AI: Done. The phone number, 555-123-4567 has been inserted into your reminder.

Explanation:

The AI expertly recognizes intention, verifies a command and provides a supplement (adding the number), demonstrating good memory and user support.

Conversational prompting is a critical component for getting large language models to engage in longer conversations. The capacity to support multi-turn conversation enables AI systems to deliver more useful and helpful interactions, particularly in applications which involve customization, on-the-fly reasoning or educational insight. As AI systems with conversational capabilities become more advanced, strategic design of conversational prompts will be instrumental to usability, accessibility, and human-AI collaboration.

### Knowledge Check 1

Choose the correct option:

- 1. What is a "prompt" in the context of generative AI?**
  - A. The code that builds an AI model
  - B. The response generated by the AI model
  - C. The input or instruction given to an AI model to perform a task
  - D. The dataset used to train the AI model
- 2. Which of the following best describes the role of prompts in generative AI?**
  - A. Prompts train the AI model from scratch
  - B. Prompts define the AI model's architecture
  - C. Prompts instruct the model on what task to perform and how to respond
  - D. Prompts eliminate the need for model tuning
- 3. Which of the following is an example of an instructional prompt?**
  - A. "Tell me a joke."
  - B. "Explain Newton's laws of motion in under 100 words for a 9th-grade student."
  - C. "Hi, how are you today?"
  - D. "That's interesting, can you say more?"
- 4. What is the key purpose of a contextual prompt?**
  - A. To initiate small talk with the model
  - B. To reduce the length of the output
  - C. To provide examples or background that help guide the AI's response
  - D. To teach the model new languages
- 5. Which of the following is NOT a common type of prompt discussed in prompt engineering?**
  - A. Instructional prompt
  - B. Conversational prompt

- C. Predictive prompt
- D. Contextual prompt

## 2.3 Crafting Effective Prompts

The quality of an AI model's output is directly influenced by the quality of its input—**the prompt**. As generative AI systems, particularly Large Language Models (LLMs), become more powerful and versatile, crafting effective prompts has emerged as a vital skill. Whether the goal is to generate creative writing, summarize a legal document, or simulate a conversation, the user's ability to structure prompts with clarity, purpose, and strategy determines the relevance and usefulness of the AI's response.

This section explores the principles of writing clear prompts, the process of refining them for better results, and common pitfalls that users should avoid.

### 2.3.1 Principles of Writing Clear and Specific Prompts

A well-crafted prompt is unambiguous, focused, and goal-oriented. It clearly communicates the user's intent to the model and often includes constraints that guide the structure or tone of the output.

Principle 1: State The Task Explicitly.

Artificial intelligence models work best when they are given a specific task. Loose queries might return partial or irrelevant results.

Example – Ineffective Prompt:

"Tell me something about history."

Example – Improved Prompt:

"Write a 150-word summary of the origins of World War I, appropriate for high school students."

This updated prompt tells the AI what the subject, word count, and audience are — elements that will assist it in formulating a response.

Principle #2: Speak Plainly and Directly

Avoid abstract or ambiguous phrasing. And employ certain action verbs such as "write," "compare," "summarize," "list" and "explain").

Example – Ineffective Prompt:

"Can you do a write-up?"

Write a 200 words article on the impression of AI in healthcare industry with one example.

Principle 3: Do Add Formatting and Styling Instructions

Specify if the output needs to be written in bullet points, paragraph, email format, table form, JSON etc.

Example:

"Name five advantages of renewable energy as bullet points."

"Below in a table construct a summary of the text with two columns, key point and explanation."

Rule 4: Identify the Audit Trail Type or Role

(However) clarifying audience or role enables the model to tune tone, complexity and style.

Example:

You are a professor of environmental science. I'm looking for a quick, easy way to explain climate change to ~20 middle school students.

Rule #5: Include some limitations (length, tone, language)

Constraints also help limit the response to what is required.

Example:

"Translate the following paragraph to French in formal business style, no more than 100 words."

### 2.3.2 Iterative Prompt Refinement

Not everything that AI generates in the very first output is perfect. One human-designed prompt, then another The model is prompted with a sentence and produces a conditioned response in the form of a score. Step 1: Try out the UXStringPromptLinq builder.

Begin with a simple prompt that describes the essential assignment.

Initial Prompt:

"Explain machine learning."

AI Output:

A generic answer, which may possibly be too complicated or very simple.

Step 2: Evaluate the Output

- Off-topic material
- No depth / structure to the piece
- Inappropriate tone

### Step 3: Modify the Prompt

Expand the prompt to include audience, format, or scope.

Refined Prompt:

“In one hundred words or less, explain machine learning in layman’s terms using a real-life example?”

Improved Output:

A (conversational) layman description and example such as "Netflix recommended movies."

### Step 4: Employ Few-shot Learning (if required)

Include prompts with examples if the task is complex.

Prompt with Example:

“Here’s one pro bio example:

John Smith is a software engineer, specializing in AI and cloud computing.

Now re-write the above Bio data taking inspiration from it for Name: Aisha Patel

Field: Data Science Years of experience: 5 years

Specialization: Natural Language Processing"

### Step 5: Repeat Until Satisfied

Refine until the model reliably generates acceptable results.

By doing so, such iteration leads to an increased accuracy while minimizing ambiguity and providing better control over the result.

## 2.3.3 Common Mistakes and How to Avoid Them

Many users, particularly beginners in prompt engineering, commit routine errors that can lead to inferior output. The following are some common errors and how to steer clear of them.

### Mistake 1: Ill-Defined or Under-Specified Prompts Example:

"Write about AI."

Issue:

Too vague — no parameters re scope, tone, structure.

Fix:

"Compose a 250-word summary of AI and its influence on education, citing examples from online learning platforms."

### Mistake 2: Stuffing the Prompt with Too Many Tasks Illustration:

"Sum up the article, give pros and cons, rewrite it for those who have difficulty following and then put your own view on top."

Issue:

More than a general process, too many instructions will make the model confused and create an incomplete or messy output.

Fix:

The tasks are broken into smaller prompts or structured formatting, such as "Step 1: Summarise the article in 100 words.

Step 2: Write down two pros and two cons."

### Mistake 3: Ambiguous or Contradictory Instructions

Example:

"You will need to write a report, its style doesn't have to be formal but it has to be very professional."

Issue:

Misfiring tone — the 'casual' clash with the 'highly professional'.

Fix:

Pick one, or explain what balance would be:

"Prepare a well-written, professional report that can be read and understood by the non-scientist."

### Mistake 4: Failing to Consider Context for Follow-up Prompts

Example:

(User has given us another four-paragraph column on climate change) "Let's pile in with pollution next."

Issue:

The AI might not remember the initial structure or format, unless context is resupplied.

Fix:

Include context:

"Write another paragraph of the type above, but rather than climate change, plug in pollution."

### In 5: Not following format instructions Example:

"Summarize the key points."

Issue:

It is possible that the AI outputs a paragraph when it would be more suitable to have a bullet list.

Fix:

“List 5 bullet points on the core aspects of this matter in less than 20 words each.

Writing good prompts is part art, part science. It requires knowing the capacity and limitations of the model being used, making clear statements about one’s request, and iteratively rephrasing one’s request based on its responses. As AI tools are integrated into the pipelines of every day, prompt engineering will be a critical skill for educators and students, professionals and programmers of all kinds.

### Did You Know?

One of the most underappreciated mistakes in prompt design is employing directive imperatives that cancel each other out — demanding a summary that be both elaborate and concise, for example. Those contradictions are often what drive AI outputs toward vagueness or incomprehensibility.”

## 2.0 Summary

AI are classified into based on what they can (Narrow, General and Superintelligent AI), how do they do (Reactive, Limited memory, Theory of mind and Selfaware) and where do they implement (Perceptual, Cognitive and Autonomous).

Author Magorki v Narrow AI is dedicated to a specific task as facial recognition, or voice assistants. General AI is an attempt to develop human-like intelligence, and Superintelligent Activity refers to theoretical intellect superior than human.

Aptitude-based classes explain how artificial intelligence systems act in response to inputs, or learn — from simple reflexive machines to high-level concept-driven self-aware machines.

Generative AI Functions to generate new content on learned data patterns. Generative models, as opposed to predictive models, allow for the generation of new outputs e.g., text, image, music and code.

Key generative model types such as the Generative Adversarial Networks (GANs), comprised of a generator and discriminator; Variational Autoencoders (VAEs) that are employed in data reconstruction through latent space, and Transformer-based models, that have proven to be especially powerful in text generation.

In the literature, Generative AI are widely used in creative content generation (Arora et al., 2017; Yang et al. But there are important ethical objections, around bias, disinformation and deepfakes.

- v Large Language Models (LLMs) are effective transformer-based models trained on an enormous amount of text corpora. They are good at summarization, question answering, translation and code generation.
- v Notable LLMs are GPT (OpenAI), BERT (Google), T5, LLaMA (Meta), Claude (Anthropic) and Gemini (Google DeepMind). These models are capable of zero-shot and few-shot learning.
- v Descendants of LLM-based tools empower applications such as chatbots, writing assistants, code generators and AI-driven search and translation engines. How well an embedding performs is dictated by the scale, quality and alignment with human instructions for that task.
- v Efficient deployment of generative AI models rely on prompt engineering. A prompt would be the input that tells the model what you want it to generate, thus its specificity and format are important since the output is chained from these.
- v Prompts may be task-focused (instructional), background or context-giving, or conversational (for multi-turn interaction such as chatbots).
- v Designing effective prompts includes principles that are focused on specificity, clear task identification, audience consideration and format regulation. This adds relevance, coherence and structure to the AI's response.
- v The iterative prompt refinement means reformulating prompts to improve results. This could involve testing, on-the-fly inclusion of initial outputs, constraints and examples to guide the model.
- v Common prompt engineering errors are ambiguous inputs, things like overloading the task, conflicting instructions and ignoring context/format advice.
- v Understanding how to design prompts allows for more effective and directed interaction with AI-driven systems, such as content creation, automation, education and decision support applications.

## 2.1 Key Terms

Weak AI – AI which is used for tasks that its users know how to perform (such as translating languages, matching available flights with desired flights, modelling puzzles, etc.); will not attain any system-wide uniform level of intellectual competence no matter how many such “isolated” tasks it can perform and never has more than a negligible amount of flexibility in what it does.

Generative AI – A type of AI that generates new content such as text, images or music having learned the patterns from existing data.

GANs – Generative Adversarial Networks, two models that compete with each other to generate realistic data.

Transformer – A class of deep learning models, such as Recurrent Neural Networks (RNN), which leverage attention mechanisms to consume sequential data in an effective manner.

Large Language Model (LLM) – A model that takes extremely large corpora of unstructured text as input and learns to understand and generate human language.

Prompt - The stimulus or query posed to an AI model in order to obtain a proper response.

Instructional Prompt – Definition of task that the AI has to accomplish clearly, e.g. summarization or translation.

Prompt Refinement: Repetitive refinement of prompts to improve prompt quality for better AI output accuracy and relevancy.

## 2.2 Descriptive Questions

What is the difference between Narrow AI, General AI and Superintelligent AI?

How do Generative Adversarial Networks (GAN)s work in generative AI?

What are some primary uses of transformer-based generative models?

What are the architectural and usage difference between LLMs like GPT and BERT?

Why is costly clarity so important in the LLMs and generative models?

What is the difference between instructional and contextual queries, give some examples.

What is iterative prompt refinement and how does it help to improve AI performance?

## 2.3 References

## 2.4 Case Study

### Enhancing User Outcomes through Effective Prompt Engineering and LLM Deployment

#### Introduction

With the inclusion of generative AI in enterprise tools, education and creative industries, organizations now have new problems on their hands when it comes to successfully deploying AI. Although models like GPT and BERT have great promise, their output is very sensitive to user input, especially the quality of prompts. This paper is a case study of how the global edtech company improved its AI-based tutoring assistant by fine-tuning the LLMs, inducing generation control and prompt engineering strategies.

#### Background

EduSmart, an edtech platform with 5M+ users worldwide, started using a generative AI assistant to help students understand textbooks material and complete their homework. Initially, the used system consisted in a transformer-based LLM pre-trained on generic data. As more and more people began to join in on this platform, several associated problems occurred including: inaccurate answers; irrelevant outputs; and not subject-specifically accurate.

Addressing these challenges unveiled a more fundamental issue: while LLM was strong, the deployment did not have domain-sensitive prompts, iterative refinement processes and adequate model alignment. EduSmart's product and AI teams teamed up to rebuild the system with structured prompt engineering and finely-tuned generative models for academic support.

#### Problem 1: The AI Assistant Provides Inconsistent or Vague Feedback

Students often got too general responses, which did not take academical and thematic context of the topic addressed by student into consideration. The source of this was found to be the unstructured and ambiguous requests made to the LLM.

#### Solution:

EduSmart adopted instructional and contextual prompts with overt format and audience information. For instance, prompts were rewritten from "Explain newtons law" to "Describe in simple terms appropriate for a high school student the three laws of motion formulated by Newton and give an example related to nature at least for one of these laws." This increased the responses to be clearer and more relevant.

**Problem 2: Absence of an Iterative Feedback** A feedback mechanism is any process by which an iterative exchange of information can carry on between users, developers, and stakeholders interested in a project.

The AI model made outputs in one step without learning from either misbehaving or partially useful responses. Students did not have a chance to narrow down or give specificity and clarity on their requests.

**Solution:**

An interactive second prompt refining interface was added where user were able to rate outputs in response and provide additional questions. The backend prompt sequences were modified according to the feedback from users, and contributed to make a response successively improved. Such multi-turn design of the conversation was proved to increase user satisfaction and lower bounce rate.

**Issue 3: Staff do not know Model Well enough to Design clean and Prompts**

Content teams producing training prompts were not provided with the skills to adequately design prompts that exploit all capabilities of the model.

**Solution:**

To this end, we created a cross-functional training on elicitation engineering principles and trained content designers to write clear, specific, role-aware prompts. Teams learned not to make mistakes like giving vague directions or passing out fatiguing prompts.

**Reflective Questions**

- How does prompt clarity impact the performance of generative AI models in academia?
- How can we iteratively refine AI-generated content?

What are the long-term advantages of teaching non-engineering teams how to do prompt engineering?

## \*% detected as AI

AI detection includes the possibility of false positives. Although some text in this submission is likely AI generated, scores below the 20% threshold are not surfaced because they have a higher likelihood of false positives.

### Caution: Review required.

It is essential to understand the limitations of AI detection before making decisions about a student's work. We encourage you to learn more about Turnitin's AI detection capabilities before using the tool.

### Disclaimer

Our AI writing assessment is designed to help educators identify text that might be prepared by a generative AI tool. Our AI writing assessment may not always be accurate (i.e., our AI models may produce either false positive results or false negative results), so it should not be used as the sole basis for adverse actions against a student. It takes further scrutiny and human judgment in conjunction with an organization's application of its specific academic policies to determine whether any academic misconduct has occurred.

## Frequently Asked Questions

### How should I interpret Turnitin's AI writing percentage and false positives?

The percentage shown in the AI writing report is the amount of qualifying text within the submission that Turnitin's AI writing detection model determines was either likely AI-generated text from a large-language model or likely AI-generated text that was likely revised using an AI paraphrase tool or word spinner.

False positives (incorrectly flagging human-written text as AI-generated) are a possibility in AI models.

AI detection scores under 20%, which we do not surface in new reports, have a higher likelihood of false positives. To reduce the likelihood of misinterpretation, no score or highlights are attributed and are indicated with an asterisk in the report (\*%).

The AI writing percentage should not be the sole basis to determine whether misconduct has occurred. The reviewer/instructor should use the percentage as a means to start a formative conversation with their student and/or use it to examine the submitted assignment in accordance with their school's policies.

### What does 'qualifying text' mean?

Our model only processes qualifying text in the form of long-form writing. Long-form writing means individual sentences contained in paragraphs that make up a longer piece of written work, such as an essay, a dissertation, or an article, etc. Qualifying text that has been determined to be likely AI-generated will be highlighted in cyan in the submission, and likely AI-generated and then likely AI-paraphrased will be highlighted purple.

Non-qualifying text, such as bullet points, annotated bibliographies, etc., will not be processed and can create disparity between the submission highlights and the percentage shown.

## Unit 3: Text & Presentation Tools

### Learning Objectives:

1. Explain what is text generation: definition, purpose, and applications in AI content creation.
2. Categorize the various forms of text generation, and describe how each is being used across businesses.
3. Study the composition of successful prompts for generating text with AI models.
4. Analyze AI models and tools in terms of their handling of prompt structure and iterative output generation.
5. Show a working knowledge of LLM and how to apply tools to create and edit text.
6. Start with Presentation or Writing Use AI-based writing and presentation tools to turn your thoughts into creative outputs for work, school, and fun.

### Content

- 1.1 What is Text Generation
- 1.2 Prompt Structure for Text Gen AI Models and Tools
- 1.3 Hands on to Text Generation, Presentation Tools
- 1.4 Summary
- 1.5 Key Terms
- 1.6 Descriptive Questions
- 1.7 References
- 1.8 Case Study

### 3.0 Introductory Caselet

#### “When the First Draft Writes Itself — Riya at PitchTank Ventures”

Riya, who is pursuing a postgraduation course in business communication, got placed as a communications associate at Startup incubator PitchTank Ventures. Among her first projects was assisting an early-stage founder with a pitch deck and executive summary for a fintech app aimed at rural India.

Short on time and needing to quickly produce well-built content, Riya went to her tried-and-true AI writing assistant. She typed a simple prompt:

“Write a business pitch for the launch of a fintech app.”

The output was disappointing. It was too vague, irrelevant and sidestepped the primary theme of financial inclusion. It simply did not sense either the region, or audience.

I had just been to a workshop on (large-scale) text generation and prompt engineering, Riya remembered. She updated her post to:

“Write an impactful executive summary (of 150-200 words) of a pitch deck for a mobile-first fintech app that strives to address the issue of financial inclusion in rural India. Concentrate on impact, scalability and simple use.” It was succinct, targeted and answered the question well. Riya handed in a draft that, with some polishing, wowed the founder and her employer.

Inspired by this, she started to experiment with increasingly sophisticated text generation instruments and slide preparation packages. She looked at the impact of prompt construction on outputs, how various models responded to repetition and how AI’s output can best serve business communication needs, whether it be writing reports, social media planning and strategy content.

After a while, Riya’s art of creating prompts and improving any AI-generated content became a significant part of her production process where she creates high-quality content in the mere fraction of time.

Critical Thinking Question:

How would you educate your team that text generators are tools, and not a shortcut to excellent and creative business communication?

## 3.1 What is Text Generation

### 3.1.1 Introduction to Text Generation

Text generation is the process of generating coherent text that would mimic a human author in its generated style. It is a subcategory of Natural Language Processing (NLP) and Artificial Intelligence (AI). The basic premise is to allow machines to write text automatically, that is coherent, contextually relevant and grammatically correct given some input, prompt or dataset. In contrast to naive rule-based systems that use predefined templates and filled slots, in the recent decades statistical, probability and neural network technologies have been employed to model the complexity of human language.

Text generation has evolved out of linguistic theories and computational methods that model how humans employ and interpret language. Initial systems were built upon n-gram models, which attempted to estimate the probability of a word in a topic by how often it appears before other words. However, these models lack the ability to capture long-term dependencies and maintain semantic coherence. The proliferation of deep learning, specifically recurrent neural networks (RNNs), Long Short-Term Memory networks (LSTMs) and now transformers has transformed the field by enabling machines to generate text that is much more natural sounding and contextually relevant.

In a word, text generation is not only about generating words in some order but also ensuring that they make sense (have coherence) and their tone of voice follows the appropriated context rules of grammar or discourse. Its usages are diverse, from little predictive text interfaces on little mobile devices to Highly advanced ones such as automatic news writing or conversational agents. The importance of this has only been building up with the rise in demand for AI-powered tools to organize and produce massive amounts of content as smoothly as possible.

### 3.1.2 Purpose of Text Generation

Text generation has multiple applications, both practical and artistic, in different areas. It just wants to save humanity from generating its own messages and do more important stuff. Several purposes can be identified:

#### Automation of Routine Language Tasks

Text generation is often the process of automatizing something that would be very time-consuming otherwise. Some of the examples are: Support response generation, Standard emails automation and Making summaries from long documents. Automation is what enables companies to grow without multiplying their labor costs.

#### Enhancing Communication Efficiency

In the field of digital communication, algorithms like predictive text and autocomplete show that machines can generate machine-assisted text for fast-paced conversation. Such systems anticipate what a user wants and suggest suitable completions, and thus save on time and effort in typing.

#### Facilitating Content Creation

The content sector depends more and more of automated writing to write articles, blogs, product descriptions and marketing copy. They help human writers by drafting or suggesting content that can then be polished. This is not to replace the creativity, but enhance it by providing language and style support.

Text generation can also be used in education for quiz question generation, text summarization, or drawing questions from passages. It is also used in language learning as a way to practice conversation and receive feedback.

### Data-to-Text Transformation

Text generation may also be used to transform structured and semi-structured data into natural language text. This is very important when considering fields like finances, meteorology or sport in which big data must be explained to people.

### Enabling Human-Computer Interaction

The evolve of virtual assistants and chat bot increase the importance of text generation task to connect humans with machines. These systems are designed to answer in human-like manner, hopefully to enhance UX.

### Creative and Artistic Exploration

There are use cases outside of the practical: text generation for creative output, like writing bad poetry, scripts and stories. It makes possible new kinds of artistic expression and collaboration between human artists and machines through form and style play.

In conclusion, automatic text generation is automation, as well as augmentation, transformation and interaction technology and creativity technology itself so that It can create enrichment and changed out of existing things even in modern society.

## 3.1.3 Types of Text Generation

There are many varieties of text generation according to the underlying method that based one, intended applications and complexity of the produced contents. It is important to know these categories, to a sense of the range:

### Rule-Based Text Generation

This is the most classic way based on predefined templates, grammar rules or substitution operations. For example, weatherr eportingsystems may customize templates such as: (1) “The temperaturetodayin[city] is[value]degreesC.” Rule-based system decisably perform well on predictable data but also the lack in flexibility as well innovation.

### Statistical Text Generation

Statistical models, such as n-grams and Hidden Markov Models (HMMs), were commonly applied prior to the popularity of neural networks. These models estimate the probability of a word given its context. They usually work for smallscale tasks and do not perform well when longer dependencies or contextual coherences of the region are needed.

### Neural Network-Based Text Generation

Towards the rise of deep learning, Neural Networks played a vital role in text generation. RNNs and Long Short-Term Memory (LSTM) models in particular, have made it possible to model language dependencies that were previously very hard to encode using statistical methods. However, for very long contexts RNNs were cumbersome.

### Transformer-Based Text Generation

The transformers were a game changer. Models like GPT, BERT and their offspring achieved highly impressive generation of text. Self-attention in Transformers allows them to learn both long and short distance relations and produce coherent, contextually aware, style-adaptive text.

### Conditional Text Generation

Such text generation is output conditioned on certain inputs, e.g. prompts, keywords or datasets. Examples include story generation conditioned on an initial sentence, and a machine translation where the output text is controlled by the source language.

### Unconditional Text Generation

Here, the system is producing text without the aid of specific external cues but rather from probabilistic imitation of a model constructed via the learning process. One popular form of text generation is called unconditional, because there is no condition on the what that will be generated. This type is often used for creative applications such as poetry or fiction.

### Data-to-Text Generation

This is the generation of natural language from structured data. Some examples are automating financial reports, sports recaps, or weather forecasts. The numbers or the records are interpreted by the systems and they are communicated in natural language.

## Interactive Text Generation

Interactive systems produce text in a responsive fashion during a conversation or cooperative task with a user.

"Learnings to Date" At Stewie, Examples: chatbots, dialogue systems and AI-driven role-playing games

## Creative and Stylistic Generation

On some systems, models are trained or fine-tuned to mimic particular styles, genres or voices. This includes producing Shakespearean sonnets or imitating the style of an author.

They are often combined in actuality. For instance, a chatbot might combine rule-based modules for targeted tasks and transformer-based models for open-ended discussion. The variety of types speak to the diversity of forms text generation can take as both a utilitarian and expressive technology.

### Did You Know?

Transformer models like GPT do not read sentences in the same way most humans do word-by-word sequentially. Instead they process an entire sentence at once using a mechanism called self-attention, and can capture longer-range dependencies and relationships in language more effectively.”

## 3.1.4 Applications of Text Generation Tools

Text generation systems have a broad range of applications in the industry, academia and daily life. As the industry, and individuals look for ways to automate new ways of communicating and creating content - their usage is on the rise. Some key applications include:

### Conversational Agents and Chatbots

Customer service and support is one of the most obvious applications, as bots can interact with users and respond almost immediately. These services use text generation to understand natural conversations, saving time and making customers happier.

### Media and Marketing Content Production

Journalists, advertisers and content creators use text-generation tools for writing articles, ad copy and product descriptions. Automated systems can produce news updates, especially in fields like finance and sports where data is structured and can be easily rendered as articles.

### Educational Tools

In education, text generation is used to generate questions automatically, abridge articles and personalized member achievements.

learning resources. Language learning apps for example use it to structure dialogues, simulate conversations and practice situations, to engage and make the learner more fluent.

### Assistive Technologies

Such text generation techniques are critical for people with disabilities. For instance, predictive text and communication aids offer people with speech disorders a way to communicate more effectively.

### Scientific Research and Data Reporting

Data-to-text systems are employed by researchers and analysts to automate generation of reports from large collections of data. They help in generating summaries of experimental results, capturing abstracts of published research and transforming raw machine databases into human-readable textual representations.

### Creative Writing and Literature

Authors play with the generation of text as a way to discover creative novelty. AI and co-creation Systems are applied to inspire and push the boundaries of poetry, screenwriting or short stories.

### Business and Professional Communication

Businesses and companies use text generation tools for writing emails, creating proposals, and taking notes during meetings. Time-saving automation tools for writing (professionalism and clarity is not forgotten.)

### SEO and Digital Marketing

Text generation applications can help to write keyword-relevant articles for websites, blogs, and e-commerce sites. They auto-generate descriptions and articles to improve search rankings and encourage engagement online.

### Healthcare and Medical Reporting

In the medical domain, text generation is applied to facilitate clinical narratives and generate structured narrative from medical notes. It is also employed for patient instruction, discharging summary and research reporting in medicine areas.

### Gaming and Virtual Worlds

Interactive storytelling in video games and virtual environments with text generation. Dynamic dialogue between character may take place, and players can have dynamic conversations with the characters.

### Legal and Financial Services

Legal practices rely on text generation to write standard contracts and provide summaries of case documents. Banks use it to generate investment summaries, regulatory-compliance reports and market analyses.

### Personal Productivity

Applications of text generation On a personal scale, auto-complete/next-word suggestions for your text messages, smart compose in emails and AI-powered note-taking assistants are common forms of text-generation services. These are tools that make life easier for both personal and business.

These applications make widely known and use text generation tools indispensable in fields which usually prioritize efficiency, scalability and personalization. They don't only increase the productivity of a process, but also redraw the limits of creativity and communication given by digital technology.

### Knowledge Check 1

Choose the correct option:

1. Which of the following best describes text generation?
  - a) The process of manually writing structured reports
  - b) The computational process of producing human-like text using algorithms
  - c) The act of translating languages word by word
  - d) The storage of large volumes of text data
2. Which of the following was a limitation of early n-gram models in text generation?
  - a) They consumed too much computer memory
  - b) They were unable to capture long-term dependencies and contextual coherence
  - c) They always generated grammatically incorrect sentences
  - d) They could not be trained on large datasets
3. What is the primary purpose of text generation in customer service chatbots?
  - a) To replace human employees entirely
  - b) To generate random conversations
  - c) To automate routine language tasks and enhance communication efficiency
  - d) To produce only marketing content
4. Which of the following is NOT a type of text generation?
  - a) Rule-based generation

- b) Neural network-based generation
  - c) Data-to-text generation
  - d) Manual narrative writing
5. Which application of text generation involves creating natural language reports from structured datasets, such as weather or financial data?
- a) Interactive text generation
  - b) Creative and stylistic generation
  - c) Data-to-text generation
  - d) Unconditional generation

## 3.2 Prompt Structure for Text Gen AI Models and Tools

### 3.2.1 Prompt Structure for Text Generation

Prompt structure describes the input used as prompt in a text generation model. In text generation systems, and particularly the so-called large language models based on transformers, the quality and clarity of the prompt decide to a great extent what will be generated. Unlike classical rule-based systems, whose outputs are heavily regulated, state-of-the-art AI models use the context of the input prompt to disambiguate meaning and help determine their output.

On the most basic level, a prompt can include anything from one word to an elaborate direction. For instance, a simple prompt like “Translate this to French: Hello,” offers an exact output while a more general prompt such as “Write a long essay on climate change” requires a longer and structured one. The source model ‘understands’ the prompt using patterns it has been trained to learn and translates the input into potential outputs corresponding to humanlike reasoning.

Prompt structures can be different according to the application:

**Instructional Prompts** – Command the system, e.g. “Summarise the following paragraph”

**Prompts with context** – Offer information that would guide the response, e.g., “You are a financial analyst. Discuss the impact of inflation on small business.”

**Examples-based Prompts (Few-Shot Learning)** – Demonstrate a desired pattern by providing input–output pairs as examples, enabling the model to generalize and provide consistent outputs.

**Open Prompts** – Leave direction at a minimum, promoting creativity and/or exploration (e.g., ‘Tell me about a robot that learns what it means to feel sorry for someone’).

The structure of a prompt thus serves as the bridge between human intention and machine reading. Well-designed prompts also increase accuracy and reduce the likelihood of ambiguous, off-topic or biased replies.

### 3.2.2 Key Components of Prompts

There are some core elements that have to be taken into consideration while designing good prompts. These are the parts which define the precision, scale and style of what model will generate as output.

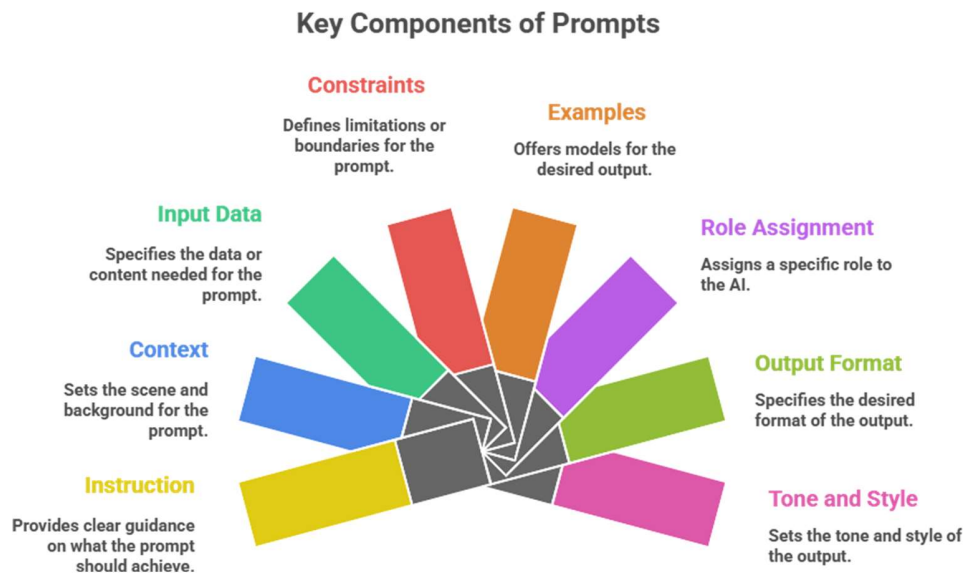

Figure: **Key Components of Prompts**

#### Instruction

Task realization is the instruction given to the model. It can be used to specify what kind of action the AI is supposed to make — it could be answering a question, creating a story, summarising text or writing code. The more unambiguous the model’s task is, the better it can align its responses with user expectations.

#### Context

The contextual information gives the background for the task. For instance, if a model is asked to “summarize the following text,” he notes, the text itself serves as the context. In more sophisticated prompts, the context can also contain role assignment (e.g., “You are an expert historian”), tone favoritism (e.g., “Explain in simple language”), or reference documents.

#### Input Data or Content

Input data is the substance that this model should act upon. For example, it could be a summarizing paragraph or a dataset to interpret, or keywords you want to turn into full sentences. But unsuitable input can also render the simplest instructions into a partial output.

Boundaries against which the model should produce outputs are determined through constraints. They may relate to word count (“Write in less than 200 words”), tone (“Use formal language”), style (“Write in a journalistic style”), or type of format (“Create in bullet points”). Assumptions can be utilized to align the generated output with that of the user’s specific requirements.

### Examples (Few-Shot Prompts)

By giving examples of the input–output patterns we want, the model can get a better grasp on what sort of structure to expect. For example:

- o Input: “Translate this: Hello → Hola”
- o Test: “Translate: Good morning → Buenos dias”
- o Input: “Translate: Thank you →”

The model learns how to continue the sequence based on the examples.

### Role Assignment

View in which AI shall respond is determined by the Role assignment. Creating a prompt to “Pretend you’re an economics professor” is a very different hand than “You are the next creative author.” And it does for genre, depth and confidence as well. This is particularly beneficial in academic or professional environments that require domain knowledge.

### Desired Output Format

Users define how they want the output to be structured — say, as an essay, bullet list, table or a certain type of code. Advert theming drive the output format which makes post processing (or not) easier, and fine control of generated text use.

### Tone and Style Indicators

Prompts can nudge the model to adopt a certain tone, e.g. persuasive, descriptive, analytical and conversational. Style markers help the model to make fine adjustments of generated outputs to specific genres (e.g. academic essays, creative narrative text or formal business communication)

Through thoughtful composition of these pieces, users can build prompts that are optimally clear, relevant and high quality in terms of generated outputs. The role of prompt engineering specifically has evolved into a speciality: it becomes prompt design, which is pivotal to maximising AI interactions.

### Did You Know?

“Instructions on tone and style in prompts can change the sound of the model entirely. For instance, requesting “Explain Newton’s Laws as a stand-up comedian” will prompt the AI to provide a funny explanation, and asking the question “Explain Newton’s Laws as a professor” will bring up a lecture-type explanation.

## Iterations of Text Generation According to AI Models

Text generation is not typically done in a single step. Iterations enable users to refine outputs, strengthen the coherence of their product and guide the results closer to the needs of evolving specifications. Various AI models and tools have various ways to iterate, which depend of their architecture and how it has been trained.

### Greedy Search vs. Iterative Sampling

Previous text generation models employed greedy search that chooses the most likely next word in each step. This produced grammatical outputs but they were often repetitive or dull. Iterative sampling methods were pointed at more diverse and natural text generation such as beam search, nucleus sampling, or top-k sampling. These techniques facilitate an iterative exploration of multiple candidate sequences ensuring that the responses are more expressive.

### Human-in-the-Loop Iterations

Some text generation models currently have the capability to have human-in-the-loop iterations on generated text. They can read outputs and ask for changes such as “make this more formal” or “flesh out point two.” They operate by generating text with different prompts. This suggestion/generation/revision feedback loop imitates human drafting process and helps in better modeling the intentions of the users.

### Multi-Turn Dialogue Iterations

Conversational agents, like chatbot AI systems, are characterized as multi-turn dialogues which occur at the exchange-level. Then, for each step from the first up to the last prompt, one can use until-then prompts-as-object that one is focusing on relevant refinements and advances. A user might start with, “Write an introduction about renewable energy,” then prompt for, “Add examples involving solar and wind power” before demanding that it be done at a high school level of writing, for example.

### Few-Shot and Zero-Shot Iterations

Iterations are made between (or within) classes of training paradigms as well. The model is trained for zero-shot examples of text with no quantity samples on general instructions. In a few-shot setting, users provide examples to condition output. By iterations I mean playing with the number and kind of examples, and repeat until you get a good output.

### Adaptive Fine-Tuning Iterations

A number of advanced systems afford iterative refinements where user actions contribute to the updates in the model. Reinforcement Learning from Human Feedback (RLHF) is a case-in-point, involving the active transmission of feedback for retraining over many loops to progressively align AI outputs with human values and preferences.

### Drafting and Revision Mechanisms

Some model applications also enable multi-draft generation, when the model generates several drafts simultaneously. And you're free to select, combine or edit draft suggestions prior to asking for final edits. This is a human creative process and can be utilized for tasks like essay writing, marketing copy or legal drafting.

## Interactive Style and Tone Adjustments

They use an iterative text generation to dynamically adjust the style. If a user, for example, were to create a business report document, they might say “Make this sound more persuasive” or “Add more technical detail.” Output is continually pruned with essential information left intact.

## Model-Specific Iteration Variations

- o GPT Models (OpenAI): leverage iterative prompting in conversational flows to algorithmically generate feedback on prompts.

- o BERT-like Models are a better fit for filling-in-the-blank (or masked language generation), in which multiple T-nodes will be processed to tinker before achieving good completions.

- o Hybrid Model which combines consideration and generation and first pooling adequate source text before generation.

Iterations thus highlight the social nature of textual production. Rather than writing in the traditional sense, AI models become a co-author and have a loop of feedbacks, context and improvements.

## 3.3 Hands-on to Text Generation and Presentation Tools

### § Hands-On to Text Generation LLMs

The large language models (LLMs) are the most advanced and used text generation system. Learning on these models in a hands-on way will provide practitioners and academics opportunities to observe how practical usage of natural language can be put to use at scale and apply AI into their domain.

- Pragmalinguistic Studies on LLMs

Fast and dirty = slow, of course – but doing LLMs in the first place has to led with fast work. Users interact with specific instances of the model class (OpenAI’s GPT, Anthropic’s Claude, Google’s Gemini, Meta LLaMA) by providing compositional prompts that yield coherent responses. Factually heuristics reveal that the output depends heavily on the quality of input. For example, the prompt “Explain gravity” would generate general explanation, but the prompt “Explain gravity in simple examples to 12 year olds.” generates contextually relevant and age-appropriate text.

### Model Parameter Tuning

These were the key generation parameters that could be tested beyhond the basic prompts itself:> -maximum-probability-if 10 selection among ten (in general) methods of probablility computing.

- Coolness – Quality of output: variety or spontaneity. Lower temperature temperatures like 0.2 leads to more predictable and reasonable text, higher temperatures such as 0.9 increase the creative element at expence of coherence.

- Top-k Sampling: In this approach, we restrict the selection of next words to a set of top k most probable choices, providing a tradeoff between diversity and quality.

- Top-p (Nucleus) Sampling: Select a set of tokens whose cumulative probability is above  $p$ , to encourage diversity for high-quality context.
- Given these, learners get a hands-on feel for how changes to the settings are changing style of storytelling, density of facts and level of creativity.

### Hands-on with Fine-Tuning and Customization

There, LLMs can be specialized with domain-dependent data for more specific tasks. For instance, a hospital could customise the model to aid with writing clinical notes, or an educational institution might customise it for use in composing exam questions. This tinkerer-friendly experience of fine-tuning also serves as an educational tool to expose what type datasets, how many training epochs, or from which model checkpoint the good quality outputs come from.

### Ethical and Responsible Use

Practical experience in studying LLM (Hands-on) also comes with the key word responsibility. A few of the biases in the generated text, facts, and improper language are evident in practice. As is learning to see and offset these weaknesses in your own work. This aspect ensures that learners do not treat LLMs as uncontested authorities but to be instruments with which to question.

### Practical Example

To demonstrate, we may write a marketing email with prompts like this:

- Type A: "Write a business e-mail about your company's new product."
- Prompt B: You are the sales manager. Write a persuasive email introducing the new software product to small-business owners 1. business owners, who cite the ease of use and potential cost savings."

Comparing the two outputs demonstrates the impact of specificity in prompt on user role.

So interactive use of LLMs is about technical parameter search, prompt manipulation and domain adaptation -- the practical literacy necessary for ethical interaction with text generation.

## 3.3.1 Hands-on to Text Generation AI Tools

The LLMs are the underlying engines, but a plethora of AI tools provide user-friendly interfaces on them. These tools are for non-technical users, so they can also democratize text generation in educational or creative or professional uses. The best way to learn these tools is to use them, experimenting with what they can and cannot do.

Popular Text Generation Tools for AI Model Below are some of the popular used AI text generators.

ChatGPT (OpenAI) – Provides conversational AI solutions for all kinds of tasks, whether it be drafting essays, summarizing documents, coding assistance or role play.

7) Jasper AI – Specifically for marketing and content writing, with templates for blog posts, product descriptions, and ad copy.

turnitin Specializes in creating marketing material such as social media posts, email campaigns, and SEO blogs

Writesonic – Offers creative and long-form content creation with integrations to chat based AI and business tools.

Quillbot – Best at paraphrasing, summarizing, and grammar rephrase work A good aid for Academic and professional writing.

### Hands-on Activities with AI Tools

- Template writing: Many tools include built-in templates such as “blog introduction,” “product description” or “LinkedIn post.” A tangible use could be the creation of similar content based on a few different templates and then analysing that data.
- Custom Tone: Choices available as tone based options, e.g. "casual", "professional" and "humorous" where user selects from the list of tones. Exploring control (Character, tone exercise) With a character tone exercise it is possible to investigate control.
- SEO and Keyword Insertion -For digital marketing-style software, they can input specific keywords and watch the AI weave them into content.
- Content Expansion and Summarization: Hands-on activities may entail typing in short notes into the tool, which automatically expands them to a fully length documents (or vice versa, summarizing long articles with digestible summaries).

### Advantages of Hands-on Tool Use

- User-friendly – Non-technical user-friendly interfaces.
- Efficiency- Production of material takes only seconds.
- Customisable – Tones, thickness & length are controlled through the touch field.

### Challenges in Hands-on Practice

- Paralysis by Analysis – If artificial intelligence is misconstrued, it’s possible that too much relying or reliance on AI would be taken and lost in the creativity.
- Fact-Checking – Results may be fake, and therefore must be verified.
- Use of ethical considerations – Discussion should take caution on the articles, plagiarism, authorship and bias under consideration.

### Illustrative Example

One mess around could be you write the intro to a Jasper AI “blog post” on “The Future of Renewable Energy” and then Quillbot or whatever sends it back shortened up. From students deciding what streamlined tool will help their writing the most.

Text generation tools: Students who work with AI text generation tools directly will build a great deal of understanding about their power, limitations and how to use them wisely in professional practice and research.

## “Activity”

Choose a single AI text generation tool (Copy, simply for example) and let loose. ai, or Writesonic. Write two varying versions of a blog introTopic: The Future of Renewable Energyduction for 1.

- For the first pass of analysis, employ the tool's default or typical settings.
  - In the second draft, tailor the voice to match your desired tone (professional, casual, persuasive) and the length.
- Compare the two outputs carefully. Write a brief analysis (150–200 words) on how features of customisation such as tone, length and topic impact the quality and nature of the content.

### 3.3.2 Hands-on to Presentation AI Tools & Models

Not just text generation but AI is also empowering the presentation space. By using the presentation AI tools to explore themselves, learners are familiarized with technology systems that integrate design automation with natural language-processing features to easily generate slides, visuals, and structured stories.

#### Overview of AI Presentation Tools

Beautiful. ai – AI Templates that automate your slide design process with presentation templates that adjust for branding.

Tome AI – A storytelling tool mixed with generative visuals and text enabling users to create presentations driven by narratives.

Canva Magic Design – AI design recommendations, from text to presentation.

SlidesAI – Guess it... converts typed text into presentation slides with a theme and style to match.

Gamma. app – You can choose AI content generation and iterative customisation for business & academic presentations.

#### Hands-on Activities with Presentation Tools

- Text-to-Slide Generation: A user inputs text, e.g., “Explain the causes of the Industrial Revolution,”

and in exchange you receive a multi-slide deck with titles, bullet points and images.

- Styling and Theming Variants: With this task, students have the opportunity to experiment with themes, colour schemes and graphical styles in order to watch the presentation change in tone.

- Iterative refinement: Text generation and presentation tools afford iteration. For example, a user may keep on generating a new slide until he/she likes the layout.

- multimedia integration They enable creation of AI pictures, diagrams or videos that may be added. For an in-class activity, students could be required to make a graph from data and insert it into a presentation.

## AI Models Powering Presentation Tools

There are typically three major categories of popular models:

- NLP models: Read the user instructions, write slide content based on it.
- Computer Vision and Design Models: Use design pattern to create beautiful layouts and ideas about icons, images or stock pictures.

Generative Visual Models: Vision models that create an image or diagram out of nothing, typically through diffusion models or GANs (Generative Adversarial Networks).

### Benefits of Getting Hands-on with AI Presentation Tools

- Time Saver- Only minutes to advanced complicated deck.

Accessibility – Not every non-designer has access to professional quality slides.

- Consistency: The use of AI also ensures the consistency in terms of type, space and visual flow.
- Encouraging creativity – Tools recommend different aspects of designs in order to provide learners with stimulus to help them explore design ideas that they may not think about.

### Limitations to Address

- Hyper Efficient – There is a chance outputs would look and sound too similar if everyone was using templates.
- Fact checking – All of the slides that are produced need to have its content checked for facts.
- Over-Depending on Tools – Students need to strike a balance between using AI as a support tool, versus having creativity and (human) machine-thought drive the process.

### Illustrative Example

In a classroom setting, one could run a hands-on exercise where the students enter a topic such as “Impacts of Artificial

**Did You Know?**

Intelligence on Employment” into SlidesAI. The tool creates a deck that students polish by weaving in academic citations, reworking visuals and tweaking the narrative. This is how AI speeds up the mechanical nature of preparing a presentation, and allows more room for human judgment and creativity.

“Some presentations with AI like Tome AI and Gamma. app integrate generative image models. “That way, a learner can type ‘a futuristic classroom,’ and they will get AI-generated visuals for slides so that you no longer need to use stock images.”

### 3.4 Summary

v Definition Modal Text generation is the automatic generation/creation of human-like text using algorithm, especially in Natural Language Processing (NLP).

v Early methods involved rule-based systems and statistical models (n-grams, Hidden Markov Models) which suffer a lack of flexibility and context.

v Modern text generation is dominated by deep learning, in particular transformer based architectures which generate coherent, contextually relevant, stylistically nuanced text.

v Text Generation Text generation spans across automating mundane language routines to facilitating communication, providing assistance in content creation thereby promoting HCI and encouraging original creative expressions.

v There are rule-based, statistical, neural network based, transformer based, conditional, unconditional, data-to-text [16], interactive [12], stylistic text generation and others.

v Summarization applications range from conversational agents, education, assistive technologies, scientific reporting to marketing [13], healthcare documentation [15], gaming [12] and legal or financial services.

v The structure of the prompt is important to the quality of generated AI text. A prompt Example prompts are instructional, contextbased, example-based or open-ended.

v Well crafted prompts include aspects like description, context, input format and constraints, examples (role), the role of the desired output (opposite of role), tone/style.

v Iterations for Text generations are the steps to improve output using greedy search, beam search, nucleus sampling and human-in-the-loop feedback.

- v Iterative methods also involving multi-turn dialogue, few-shot and zero-shot prompting, adaptive fine-tuning, drafting & revising mechanism and style control.
- v Direct manipulation of Large Language Models (LLMs) such as GPT, Claude, and Gemini to explore prompt selection, model parameters (temperature, top-k, top-p), and fine-tuning.
- v Ethical Application LLMs must be used responsibly, being self-aware and acknowledging the potential biases and inaccuracies of generated text.
- v These methods combine an NLP model for text treatment, a visual design model for layout generation and a generative visual model for illustrations.
- v On the practical side, it includes creating slides from text input, theme customization, iteratively refining outputs and including multimedia elements.
- v Opportunities of an AI-presentation tool are efficiency, accessibility and better creativity, but challenges include over-standardization, content verification and template dependency.

### 3.5 Key Terms

- 4 Text Generation – AI generated output that reads like text written by a human, according to input prompts or data sources.
- 5 Prompt: Intake or input given to an AI model that influences its text output.
- 6 Transformer Model – A type of neural network structure which is good at processing and generating language by making use of the self-attention.
- 7 Few-Shot Learning – A prompting based model that is provided only few examples to generate output.
- 8 Beam Search - A decoding approach which generates multiple sentence continuations in an iterative manner in order to choose the optimal text continuation.
- 9 Fine-Tuning – The tuning phase of a pre-trained model when it is adjusted for performance over a specific domain or dataset.
- 10 Nucleus Sampling – A stochastic approach for text generation which regards words as picked from the minimal probability mass larger than a certain barrier.
- 11 Presentation AI Tool – An app that would automatically generate, format and refine presentation slides based on user inputs using AI.

## 11.0 Descriptive Questions

What are the differences between rule-based, statistical and transformer based methods of text generation?

1.3 Name and explain three primary motives behind text generation in contemporary applications.

How is Instructional, Contextual and Example-based Prompting different in steering AI models?

How do prompts constraints affect the design of a prompt and its generation process?

Describe the idea for humans-in-the-loop iterations in generation and give an example of that.

What are the ethical issues in hands-on work with LLMs?

Name three characteristics of AI text generation software like Copy or Jasper. ai and applications of them.

How do presentation tools using AI NLP and generative visual model create slides?

## 11.2 Case Study

### Enhancing Learning and Productivity with AI-Based Text and Presentation Tools

#### Introduction

The tremendous advances in the quality of generated texts brought about by artificial intelligence have changed the way for people and organizations to communicate, learn, and create. From academia to the enterprise, Large Language Models (LLMs) and AI-powered presentation platforms are changing the game on efficiency, accessibility and creativity. This case study is about AI tools that do a good job. These AI enhanced tools help make and show text in places where people learn and work. They do this to help people get work done learn new things and come up with new ideas. The AI tools are used in learning environments and work environments to make things better. The main goal of these AI tools is to improve productivity help people learn and stimulate innovation, with the AI tools.

#### Background

We are making progress with the help of Natural Language Processing and Large Language Models like GPT, Claude and Gemini. These tools allow people, like learners and professionals to have conversations with machines that feel more natural and take into account the context. At the time services like ChatGPT, Jasper AI and Copy.ai are making it easier for people who are not tech experts to create content. They do this by providing interfaces that're easy to use. For example services, like Beautiful and others are also being worked on to make things simpler. ai, Tome AI and SlidesAI provide an easier way to create structured looking

beautiful slides without having to do it manually. Universities in particular are under pressure to produce learning resources more efficiently, yet engage students more successfully. Members of the business community also need to have their reports, proposal and presentations drafted as efficiently as possible in order to compete with tight schedules and fast moving markets. AI empowered tools are solving these problems head on, by automating repetitive tasks, boosting design consistency and scaling creativity.

### Problem 1: Time-Consuming Content Creation

Both students and professionals struggle to produce large amounts of content in their timeframes. Manual writing is a lengthy process, and it is easy to lose motivation which leads to incomplete or low-quality articles.

Solution:

AI text generation tools assist by creating first drafts, expanding notes into full-length essays, and providing alternative phrasing options. With role-based prompts, tonal tweaks, and scenario suggestions you can increase content creation speed while simultaneously improving content quality.

Issue 2: You're Bored at the Meetingudevcom. Software: Presentations are Booooooring.

The task of creating an interesting, appealing presentations can be difficult for educators and professionals. There is even an art to creating slide presentations but let me tell you what I'm starting to dislike about it is the tediousness of making new slides; low chance for inspiration everything being so influential boring. Solution:

AI-driven presentation tools automatically create slides from text input, add beautiful design templates, and recommend visuals. This provide a consistent format and helps engage the audience to enable presenters concentrate on conveying their message effectively.

Issue 3: Sparse Prompt Engineering Knowledge We notice that prompt engineering is not fully understood.

Therefore, many users struggle to get useful suggestions out of LLMs because they don't know how to pose effective prompts. Bad prompts result in garbage or generic answers.

Solution:

Prompt Design Training Prompts designed using instructions, context, examples and constraints enables users to elicit high-quality responses from the model. Iterative interactions allow iterative refinement to ensure outputs are consistent with the user's goals.

#### Reflective Questions

How can educational institutions incorporate AI summarizing text and presentation tools that maximize teaching and Learning Outcomes?

How does prompt design impact the quality and fidelity of AI text?

How can professionals reconcile the dependence on AI and maintain originality and critical thought?

38,314 Characters

## \*% detected as AI

AI detection includes the possibility of false positives. Although some text in this submission is likely AI generated, scores below the 20% threshold are not surfaced because they have a higher likelihood of false positives.

### Caution: Review required.

It is essential to understand the limitations of AI detection before making decisions about a student's work. We encourage you to learn more about Turnitin's AI detection capabilities before using the tool.

### Disclaimer

Our AI writing assessment is designed to help educators identify text that might be prepared by a generative AI tool. Our AI writing assessment may not always be accurate (i.e., our AI models may produce either false positive results or false negative results), so it should not be used as the sole basis for adverse actions against a student. It takes further scrutiny and human judgment in conjunction with an organization's application of its specific academic policies to determine whether any academic misconduct has occurred.

## Frequently Asked Questions

### How should I interpret Turnitin's AI writing percentage and false positives?

The percentage shown in the AI writing report is the amount of qualifying text within the submission that Turnitin's AI writing detection model determines was either likely AI-generated text from a large-language model or likely AI-generated text that was likely revised using an AI paraphrase tool or word spinner.

False positives (incorrectly flagging human-written text as AI-generated) are a possibility in AI models.

AI detection scores under 20%, which we do not surface in new reports, have a higher likelihood of false positives. To reduce the likelihood of misinterpretation, no score or highlights are attributed and are indicated with an asterisk in the report (\*%).

The AI writing percentage should not be the sole basis to determine whether misconduct has occurred. The reviewer/instructor should use the percentage as a means to start a formative conversation with their student and/or use it to examine the submitted assignment in accordance with their school's policies.

### What does 'qualifying text' mean?

Our model only processes qualifying text in the form of long-form writing. Long-form writing means individual sentences contained in paragraphs that make up a longer piece of written work, such as an essay, a dissertation, or an article, etc. Qualifying text that has been determined to be likely AI-generated will be highlighted in cyan in the submission, and likely AI-generated and then likely AI-paraphrased will be highlighted purple.

Non-qualifying text, such as bullet points, annotated bibliographies, etc., will not be processed and can create disparity between the submission highlights and the percentage shown.

## Unit 4: Visual & 3D Tools

### Learning Objectives:

Build efficient prompts for AI image generators like DALL-E, Midjourney or other relevant systems.

Knack around on how to create and refine AI-generated imagery with real experience involving the leading tools.

Leverage AI tools to produce logos, infographics and visual assets for creative or business needs.

Discover what AI can do for converting sketches to renders and modelling 3D shapes.

Develop 3D virtual worlds with AI tools, and analyze how they can be used in various fields.

## 4.0 Introductory Caselet

### “Design Beyond Imagination — Kartik at NuSpace Interiors”

A final year student, Kartik started his internship at NuSpace Interiors, a design consultancy specializing in marrying futuristic looks with intelligent technologies. On the second day, he was thrust into a project to imagine future living scenarios for a tech client’s penthouse — with an emergency pitch presentation needed in 48 hours.

With no time to hand sketch or create from scratch in 3D modeling, his mind went back to an AI image generation tool he had played with at a college workshop. He typed:

“Create a luxurious, minimalist tech-inspired living room with high-resolutions and ambient lighting on the floor that is made of white marble which measures 3600mm (width), 2100mm (length) and suitable modern furniture.”

Seconds later, the tool displayed half a dozen photorealistic choices. He refined the prompt with more context and design constraints. The end product was not only a visually-stunning image, but one that described and fit the client's needs.

The team put it in the pitch, which ultimately sold.

Invigorated by the outcome, Kartik started looking at other AI design tools. He leveraged them to make logos, build custom infographics and even render his hand-drawn sketches into 3D images. Using prompt structure and the powers of AI to test out creatives quickly turned around visual concepts far more successfully for Kartik.

It changed the way Kartik thought about design workflows — instead of substituting for creative spontaneity, they could be an efficient complement to it.

Critical Thinking Question:

As Kartik, how would you explain to a senior designer that the AI tools in visual creation are not to take shortcuts but multiply speed, iteration and creative discovery.

## 4.1 What is Image Generation

### 4.1.1 What is Image Generation

Image generation is the task of generating images through artificial intelligence (AI) models and methods. In contrast with traditional digital illustration, photography or computer graphics — where humans have to digitally design, illustrate or capture visual content — AI models can automatically generate new imagery from data, text-based description or even reference images. This is the heart of contemporary artificial intelligence research and one that has implications in a multitude of areas -from education to entertainment, design and healthcare - further afar.

The first early success was spawned by Generative Adversarial Networks (GANs) in 2014. GANs are made up of two adversarial networks: one that generates images and the other evaluating whether an image looks real. With time, the generator learns how to generate a picture that discriminator can't tell is a photo or not. GANs have been used, for instance, to create fake celebrity faces that don't resemble anyone real — and show how machines can learn the patterns of realism.

More recently, diffusion-based models such as Stable Diffusion and DALL·E are reshaping the field. These models begin from noisy inputs, and are able to gradually evolve them into a meaningful picture based on the user's input. For example, when a user types "A red panda riding a skateboard in Times Square, digital art style," the model breaks down the text and gradually generates an image that meets that description.

Illustration 1: A biology teacher can create cellular-diagram images by typing "A highly detailed illustration of human cell with mitochondria, nucleus and ribosome marked with bright colors" etc. The tool generates classroom ready resource in minutes not hours and does not require stock photos or pre-drawn sketches.

Example 2: A video game developer could ask for concept art by typing in a prompt like, "A futuristic spaceship soaring over a neon-soaked cityscape — cyberpunk." Designers, instead of waiting weeks for draft sketches, receive a variety of visual interpretations on the spot.

Ultimately, image generation combines the computational efficiency of a machine with the creative freedom of an artist to create images that would take much longer and require substantial handwork.

#### Did You Know?

"Diffusion-model-based ai image synthesis (eg, Stable Diffusion and DALL·E 2) begins with random visual noise and slowly erodes it step by step toward a structured image consistent with the prompt. It is inspired by how images get degraded as you add noise over time, but an AI system can learn to reverse it."

### 4.1.2 Prompt Structure for Image Gen AI Models and Tools

Artists are guided by prompts just as AI models are when they generate visuals. The prompt is the input (text, picture, or both) that tells the model the kind of image to produce. A good prompt can make some ill-defined suggestions turn into the most detailed, vivid imagery you've ever seen, while a bad one can lead to an opinionated or inferior image.

## Components of Effective Prompts

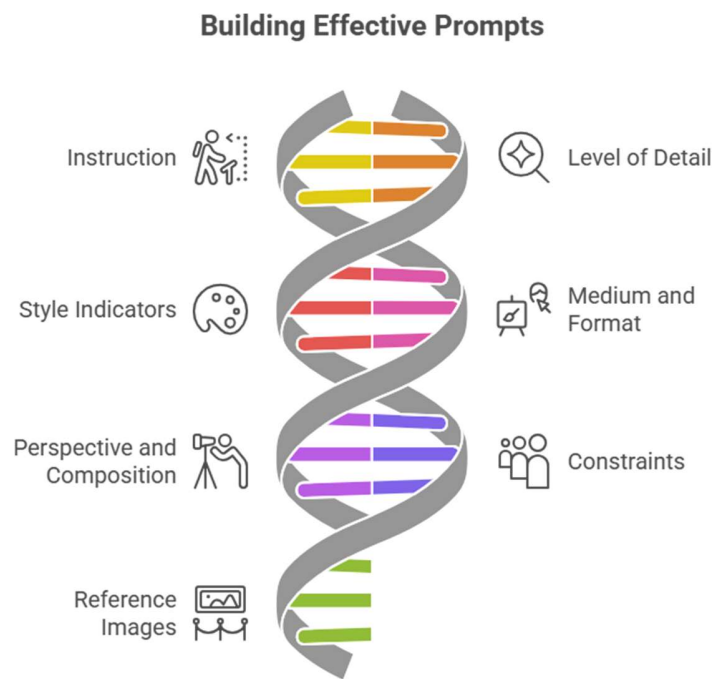

Figure: Components of Effective Prompt

#### 1. Instruction (Core Idea)

The main thing that the writing is, about should be easy to understand from the prompt. The prompt is very important because it tells you what the central subject of the writing is. You need to know what the central subject is so you can write about it. The central subject is the idea that the writing is trying to get across.

For example if you say "a mountain landscape at sunrise" that gives a clear idea of what you are looking for. On the hand if you just say "mountains" that is not very specific and you may get all sorts of different mountain things. So it is better to say "a mountain landscape at sunrise" because that tells people what kind of mountains you want to see. This way you get mountain landscape pictures that have mountains in them and the mountains are at sunrise which is a nice time of day, for mountain landscape pictures.

## 2. Level of Detail

Adding adjectives, settings, or contextual details enhances precision.

o Example: "A snowy mountain landscape at sunrise with a river in the foreground and pine trees on

The side makes the picture look more complete. It helps us see the scene. The side is important, for a complete visual scene.

## 3. Style Indicators

People can tell a computer what kind of art style they like. For example they can say they want something that looks like it was painted by an artist or something that looks really futuristic. The computer will then try to make a picture that looks like the art style that the person asked for. Art styles are things like the way something is drawn or painted. People like art styles like some people like old fashioned paintings and some people, like really modern computer generated pictures. The computer can make all kinds of art styles like paintings or drawings or even things that look like they were made by a machine.

For example when you ask for "A portrait of a woman, in the style of Van Gogh" the picture that comes out has a textured and impressionistic look, just like the paintings that Van Gogh did.

For example when you say "A city skyline, cinematic lighting" it makes a picture that looks really real like it is, from a movie. This is because it uses lighting that you would see in a film, which makes the whole thing look more realistic.

## 4. Medium and Format

When you define the medium the outputs will be what you want them to be. This is because the medium is what makes sure the outputs of the medium are good, for the thing you are trying to do with the medium.

- o Example: “A 3D render of a coffee mug with realistic lighting” vs. “A watercolor painting of a coffee mug.”

## 5. Perspective and Composition

Including camera angles or perspectives controls framing.

For example when you look at a chessboard from the top it is very different from looking at a chess piece on the chessboard up close. The view of the chessboard from the top gives you a lot of information about all the chess pieces and how they are arranged. On the hand a close-up of a chess piece, on the chessboard shows you all the details of that one chess piece. These two views of the chessboard and the chess piece are not the same all.

## 6. Constraints

People usually need things to be a size or have certain qualities. They want the dimensions or qualities of something to be just right for what they need. Users often look for dimensions or qualities, in the things they use.

- o Example: “A realistic 8K resolution landscape with no text in the background, aspect ratio 16:9.”

## 7. Reference or Example Images

Some tools let people put up a drawing or picture to start with. These tools allow users to upload a sketch or photo.

The fashion designer, for instance, could upload a drawing and make the following statement: "Transform this sketch into a complete design for a piece of clothing". The fashion designer would like to enhance the sketch and have it looks really beautiful. They want the sketch to become a design of something like a dress or shirt. The designer is hoping to get the sketch right, perfect enough for a fashion magazine or a clothing store. realistic runway outfit, pastel colorpalette.”

Types of Prompts with Examples

- Descriptive Prompt: “Realistically styled lion lying under a tree in the African Savannah.
- A lion in Japanese water colour style ” Here is your stylistic prompt!
- Task Prompt: “Create an infographic of human respiratory system with labels”
- Hybrid Prompt: Posting a sketch of lungs with the heading, “Recreate this image digitally within\_HALF\_INK.”

labeled anatomy in high resolution.”

### Importance of Iteration

Many times, the first try does not get us what we expected. Iterate and refine your prompts constantly.

· Example Iteration:

So first prompt: “Robot in a park.”

o Clearer prompt: “Cartoon robot playing chess with a kid underneath cherry blossom trees in park, pastel colors.

o More refining: “Cartoon-style robot playing chess with a child under cherry-blossom trees in a Japanese park, wide-angle view, watercolor-effect.”

Each line trains the model based on a more detailed set of criterion until I obtain the result i want.

This iterative process demonstrates why step conditioning is an important skill for image generation.

### “Activity”

Draft three prompts to generate an AI image of the same subject: “A library.”

- When you start do not make it complicated. You should just say something, like "A interior".
- In the prompt I want to add some details. The place I am thinking of is a library interior. This library has glass walls and wooden shelves. The library also has lots of space and the wooden shelves are filled with books. The modern library interior has glass walls that allow natural light to come in. The wooden shelves are really nice. They have lots of modern library books on them. I like the library interior because it is nice and quiet and it has glass walls and wooden shelves. The modern library interior is a place to study and read modern library books.

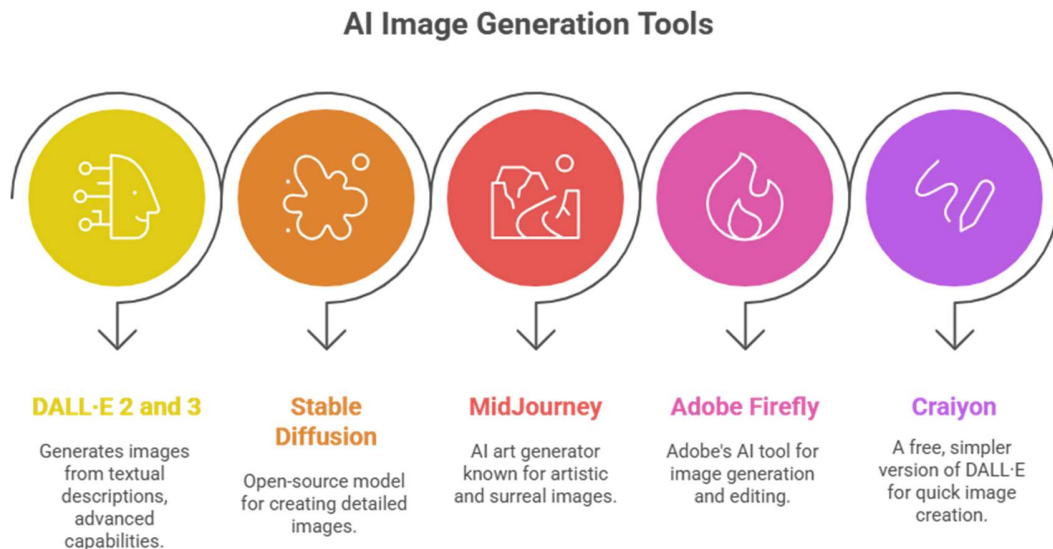

Students are doing their studying.

- When you get to the prompt you need to say what style and constraints you want for example: "I want a modern library interior and I want it to be made in a 3D render style and it has to be ultra.

realistic, with warm lighting, aspect ratio 16:9.”

Run these prompts in an AI image generation tool (such as DALL·E, Stable Diffusion, or MidJourney). Compare how each output differs in terms of detail, realism, and composition. Submit a short reflection (200– 250 words) explaining how prompt complexity and structure influence the generated visuals.

### 4.1.3 Hands-on to Image Generation AI Tools

Direct manipulation of visual generation tools is important to achieve real literacy. Sample projects work with a user's knowledge of technology but also empowers them to use their creativity in both artistic and practical senses.

#### Widely Used Tools

##### DALL-E 2 and DALL-E 3 (OpenAI)

Strengths: High quality, open-ended pictures and detailed word prompts.

Example: A marketer types, "A flat design vector logo of a coffee cup steam in the shape of a lion cloud." The model instantly generates several logo variations.

##### Stable Diffusion

Strength: Open-source and highly customizable.

Example: A lab at the university hand-tune Stable Diffusion for ancient artifacts to produce visual reconstructions of damaged archaeological findings on datasets.

##### MidJourney

Strength: Artistic, funky results.

E.g. – Fantasy Novelist designing the cover for his latest fantasy novel offers a prompt as follows "A Dragon in flight over an ancient castle with highly detailed and epic looking fantasy artwork." MidJourney produces multiple concept designs.

##### Adobe Firefly

Strength: Specialized in Adobe for professionals.

Example: A graphic designer working on an ad banner can utilise Firefly's "text-to-image" tool to replace dead space with a product shot relevantly generated in the same style.

## Craiyon (DALL·E Mini)

Weakness: A little on the casual side.

Example: Students trying AI art for school projects can create fun, lightweight visuals such as “A cartoon elephant playing soccer.”

## Hands-on Learning Activities

- Experiment with Styles:

Generate the same subject in multiple styles to observe differences.

- o Prompt A: “A medieval castle, realistic photography.”
- o Prompt B: “A medieval castle, oil painting.”
- o Prompt C: “A medieval castle, LEGO block style.”

This shows people how the words we use can change the way art is made. The way we say things the wording of a prompt can really change the direction of a project. When we use words to describe what we want it can completely alter the way the art turns out. The prompt wording is very important because it sets the tone, for the artistic direction.

- Editing through Inpainting:

Imagine you are at the beach. You photograph the beach scene. Now you want to transform the sky in the photo into a sunset. You can ask the computer to swap out the sky with a sunset. This is one way to look at how computers can assist in the design process.” The computer can alter some parts of the picture to make it look beautiful. This just goes to show that computers can be good for us when we are doing designs. We have the ability to use computers in order for our pictures to look better. For instance, let’s say that we may want to use the computer to remove the sky and replace it with a sunset in our beach scene picture.

- Poster Design:

If students have to create a poster for World Environment Day, they could consider what the backdrop on that poster would be. For instance, they can think of a forest and it's really green and there are a lot of different animals inside. They can even sketch this forest on the computer. Then, they can place this background into their poster to make it appear fancy. The background could be a photo of, say, a green forest, with various kinds of animals that have been generated by the computer program which can make digital pictures. This will be included in their end of World Environment Day poster project.

## Applications in Education and Professional Life

### 1. Art and Design Education

Students get to try out styles and color schemes and learn how to tell stories with pictures even if they are not great artists. For example a student who is studying design can try making "minimalistic architecture renderings" for their class projects. They can do this to see what works and what does not work for the design student and to learn more, about minimalistic architecture renderings.

### 2. Business and Marketing

Companies are using computer made pictures for ads that're just for certain people. For example a website that sells

things can ask for "A picture of sneakers, on a fancy background that looks good on Instagram."

### 3. Research Visualization

Environmental scientists might ask for a picture that shows how the sea levels are going up and affecting cities near the ocean. This picture would be, like a chart, called an infographic that helps us understand what is happening to cities because of rising sea levels.

style" to quickly visualize data trends.

### 4. Cultural Reconstruction

Historians use AI to recreate "Roman city streets as they may have looked in the first century." While speculative, these visuals aid in teaching and exhibitions.

## Ethical and Practical Considerations

- Ownership: If any image sampled is close to an artwork found in the training data set, copyright and ownership issues arise.
- Bias: Prompts like "I want to see a portrait of a CEO" could propagate cultural or gender stereotypes if the training data contains bias.
- Risks of Misinformation: Hyperrealistic AI-generated images could contribute to the spread of fake news or deepfakes, and present ethical dilemmas as well.

Example of ethical considerations: In 2023, AI-generated images of political leaders were circulated widely on the internet and created mass confusion between what was real and what wasn't. This underscores the need for transparency and digital literacy in such AI solutions.

### Learning Through Experimentation

It allows learners to poke at their vision of As in action and see what they really are capable (or not) of. A well-formed exercise would challenge students to:

Paint us a picture in words of "A classroom of the future where artificial intelligence enabled robots are teaching children."

Compare the outputs of different tools (DALL·E vs. MidJourney).

Consider those in realism, style and usability.

Such activities marry theoretical knowledge with hands-on practice to support learners in using AI tools in meaningful and ethical ways for learning, work, and play.

## 4.2 Visual and 3D Tools Hands-on

- 4 The Future of Text-to-Image Generation Will Make You Sad When artificial intelligence gives birth to diversity-including even color-it will have finally laid the lid upon the monotony of text generation. Advertised Today, AI powers brands such as advanced visual graphics and 3D software tools for designers, marketers, educators and students to make logos, infographics, 3D renders and immersive experiences like

never before. They are not a replacement for the human mind, but add to it as tools that increase workflow speed, hint at design ideas and automate repetitive work. Working with these tools gives students the opportunity to explore ways to narrow the distance between what they imagine and whatever does or does not emerge from their imaginations, on how they make ideas into things.

### 5.0.1 AI-driven Logo Design

Brands are both in need of, and the sum of their logos -- symbols that reflect, communicate and embody meaning, value and identity in visual form. Logos were historically the result of laborious back-and-forths between graphic designers and clients. With AI, this is a natural way of working and you can do logo concepts (based on text, keywords or industry style) in seconds.

Example: A food delivery startup might submit: “We need to design a modern, minimalistic logo that has a green color scheme which represents scooter and basket of food.” AI-assisted design tools like Looka, Hatchful by Shopify or Tailor Brands spit out a flurry of variations in seconds.

Hands-on Exploration:

- Students may practice responding to such prompts as:
  - o “Futuristic” Break on through to the future with a circular logo for technology companies that features a graduated blue swatch of color.
  - o “Chic monogram logo for a fashion brand with black and gold color”
- By comparing outputs, they learn how prompts and color specifications and style cues shape the brand’s perceived identity.

Application: Marketing or business students create logos for fictitious brands, and then analyze which designs are most congruent with the brand’s values. The exercise also illustrates limitations — AI can create pretty logos, but perhaps not with a lot of originality or cultural sensibility.

### 5.0.2 Infographics

by Kristen Chandler Infographics are a mix of pictures, icons and words that help explain information. They are popular with educators, companies, and journalists etc. AI powered infographic generators streamline the process by generating layouts, sample with color schemes coupled with icons/illustration that matches with your theme.

Example: A researcher that wants to share survey data on renewable energy adoption can use AI tools such as Canva’s Magic Design or Piktochart. For example, by uploading raw data or entering a prompt like “Infographic on percentage adoption of solar/ wind/ and hydro in 2023”, the layout with visuals are prepared professionally.

Hands-on Exploration:

- Students could begin by producing an infographic on “Causes and Effects of Climate Change”.
- They input text, and the AI tool synthesizes visuals, flowcharts and icons to match the script.

- Students can use the dropdown to see how the infographic changes depending on tone – educational, professional and playful.
- **Practical Implication:** This exercise helps students learn about literacy. Students are taught how to look at data in a way. They also learn why it is useful to do this and what things they should think about when they visualize data, like this. The digital literacy that students learn from this exercise is very important. The exercise teaches students about the importance of literacy and how to use it to visualize data.

### 5.0.3 Sketch to Render

The AI has a cool skill. It can take simple drawings and make them look super professional. This is really useful when you are working on building designs product designs and artwork. Students can start with drawings and the AI will create a realistic picture or design concept. The AI is great, at taking these drawings and making them look like they were done by a professional. Students can use this feature to make their building designs product designs and artwork look really good.

For example an architecture student draws the front of a building. Then they put their drawing on a computer service like Autodesk Sketch-to-Render AI or Stable Diffusion with ControlNet. This service makes a picture of the building that looks real with things like sunlight different textures and the materials it is made of. The student gets to see what the building would look like in life with all the details like lighting and materials using the Autodesk Sketch-to-Render AI or Stable Diffusion, with ControlNet service to make the picture.

Hands-on Exploration:

People draw a chair design on paper and then they scan the chair design. They want to see what the chair design looks like on a computer. The simple chair design is now, on the computer because they scanned the chair design.

- The Artificial Intelligence system comes up with kinds of interpretations such, as wooden or metallic or minimalistic or even sci-fi interpretations. The Artificial Intelligence system thinks about things in ways like wooden interpretations or metallic interpretations or minimalistic interpretations or sci-fi interpretations.

- Learners then look at the two styles. Think about what they are used for, like furniture for your home versus chairs, for a modern office.

### Did You Know?

**Practical Application:** This approach speeds up design prototyping. Where traditional rendering can take hours, A.I. functions with extremely fast turnarounds. For students, it shows how early-stage imagination can transform into physical designs without the need for much technical expertise.

Some AI sketch-to-render tools, however, can even interpret very rough doodles or incomplete outlines and still generate a realistic rendering. For example, an input triangle with two circles might be identified as the skeleton of a car drawing that the AI can then fill in and expand to form a realistic car image.”

### 5.0.3 3D Modelling with AI

3D modelling tends to be involved with complicated software like Blender, Maya or 3ds Max. AI is now automating this, generating 3D assets from just text descriptions or even 2D images.

**Example:** Prompt like “3D model of a medieval sword with rich golden handle” can result in ready to use 3D assets. Some tools — like Point-E (OpenAI), Luma AI, and NVIDIA’s GET3D, among others — are designed to turn text or images into 3D meshes.

**Hands-on Exploration:**

- Learners input: “3D model of a futuristic electric car, glossy black surface, in an aerodynamic shape”.
- The AI outputs a mesh model that can be rotated, scaled, and brought into 3D clothes program.
- STUDENTS analyze how specificity in prompts (e.g., “with glowing headlights” vs. “with matte finish”) impacts the geometry and texture of their solutions.

**Practical Application:**

In education, for example biology students can create 3D models of cells, organs or molecules for an interactive educational experience.

- In engineering, Tools / parts of product produced as prototypes can be visualized in very less time before the physical production.
- In gaming, designers can make characters, objects or environments from prompts without investing time in early stage designs.

Through hands-on experimentation, students understand how AI democratizes 3D modeling, leads to semi-automated and automated approaches that allow non-experts operate these tools and inspires professionals in the field.

## 5.0.4 Immersive 3D Environment Creation

The final frontier of visual tools is the development of immersive 3D environments, full virtual worlds that users can access in gaming, simulations or in virtual reality. AI contributes by automating terrain generation, populating environments with objects, and matching realistic textures and lightings.

Example: For game design, a developer may type: “Generate tropical island terrain with palm trees, sandy beaches, hidden caves and clear blue water.” With tools like NVIDIA Omniverse, Unreal Engine and AI plugins or Unity’s generative features we are able to generate landscapes in days that would have taken weeks to design.

Hands-on Exploration:

Learners input: “An ancient Egyptian desert setting with pyramids, ruins and sunset lighting.

- The AI builds a 3D space you can navigate.
- Students can select between options like “torches along the pathway” or “an oasis in the distance.”

Practical Application:

- For education, students studying history can virtually wander around reconstructed cities such as Rome or Mohenjo-Daro.
- In construction, customers can walk through a building before it goes up.
- In corporate training, safety drills or customer interactions can easily benefit from immersive simulations.

Through exposure to these tools, students understand how AI connects imagination and experiences – forging this new path in virtual design.

Integration Across Subtopics

This, combined with AI-based logo creation, infographic generation, pen-to-pixel drawing translation and 3D modeling, plus the generation of immersive environments represents a wide range of AI’s involvement in visual creativity. All of these tools focus on accessibility: Makers are able to create professional looking visual and/or environments, even without advanced art and technical training. But with this great power comes great responsibility. Do-it-yourself experience in those areas helps students learn to think critically, get creative with experimentation and partner with AI tools instead of having machines replace them.

### Knowledge Check 1

Choose the correct option:

1. Which of the following best explains AI-driven logo design?
  - a) It creates logos by randomly selecting colors and shapes.
  - b) It generates logos instantly from prompts, keywords, or themes using AI models.
  - c) It replaces all human designers completely.
  - d) It only works for multinational corporations.
2. Which AI application is most useful for transforming raw survey data into visually engaging charts and layouts?
  - a) Sketch-to-render
  - b) Infographic generation tools
  - c) GAN-based image synthesis
  - d) Immersive 3D environment creation
3. In sketch-to-render workflows, what is the role of AI?
  - a) To manually redraw sketches in graphic software
  - b) To convert rough outlines into refined and realistic renders
  - c) To automatically print sketches on paper
  - d) To erase incomplete sketches from datasets
4. Which of the following is an example of AI-based 3D modeling?
  - a) Creating a clay sculpture by hand
  - b) Writing HTML code for a website
  - c) Generating a mesh model of a futuristic car from a text prompt
  - d) Editing a photo in Photoshop
5. How can immersive 3D environments generated by AI be applied in education?
  - a) By letting students walk through reconstructed historical cities virtually
  - b) By only showing 2D diagrams of concepts
  - c) By producing only static logo designs
  - d) By replacing textbooks entirely without context

## 5.1 Summary

- Experiment with Styles:

Generate the same subject in multiple styles to observe differences.

- o Prompt A: “A medieval castle, realistic photography.”
- o Prompt B: “A medieval castle, oil painting.”
- o Prompt C: “A medieval castle, LEGO block style.”

This shows people how the words you use can change the way something is made to look. The words you use in a prompt can really change the direction of something. When you are making something the words you use to describe it can make a difference, in how it turns out. The prompt wording is very important because it can shift the direction of a project.

- Editing through Inpainting:

Let us take a picture of a beach and ask the computer to change the sky to a sunset. This way people who are learning can see how these computer tools can make changes to pictures, which shows that they can be used in many different ways when designing things.

- Poster Design:

Students who need to make a poster for World Environment Day can consider what they would like the background to be. They might draw a picture of this forest and it's really green, there's lots of different animals in it. They can draw this picture on the computer. They can then overlay this background to their poster, so that it appears pretty. Background is the part of it for World Environment Day poster.

Image generation is how a computer generates a picture with the help of computer programs. These programs are referred to as AI models. They don't make drawings by hand. Follow a set of rules. Instead they utilize information in the data. Guess to create the pictures. The task of creating images is very good, at its job of picturing things that look real. It uses AI models to do this.

on people made some big discoveries with something called GANs. These GANs employed a generator and a discriminator that worked together to create images that were incredibly, kick-in-the-pants real. Now we have stuff, like DALL·E and Stable Diffusion. Such DALL·E and Stable Diffusion models can draw detailed images from noise alone, and they improve when you give them hints, which are known as prompts to the DALL·E and Stable Diffusion models.

Generative models of images are really good at learning from collections of images.

They look at these pictures. Try to understand what things look like.

Image generation models then use this understanding to create pictures based on what the user tells them like a sentence or a simple drawing.

Image generation models are very useful because they can make pictures that are similar, to the ones they learned from.

\* Prompts are really important when it comes to telling AI how to generate images.

The AI needs to know what you want it to do.

You have to give the AI image generation instructions and tell it how much detail you want.

You also have to let the AI know what style you like. What kind of medium you want the image to look like.

The AI needs to know how to compose the image

Sometimes the AI does not get it right the time so you have to try again to get the image to look the way you want the AI image generation to look.

This is called iteration. It is a big part of working with AI image generation.

There are kinds of prompts. These include prompts that focus on subjects. Then there are prompts that emphasize art styles. You also have prompts, like infographics and diagrams.. Then there are hybrid prompts that combine text with images. These types of prompts are all unique. Serve different purposes. The types of prompts include prompts, stylistic prompts, functional prompts and hybrid prompts.

\* There are some cool image generation tools out there, like DALL·E, Stable Diffusion, MidJourney, Adobe Firefly and Craiyon.

They're tools for people to experiment with styles, and points of view.

They also have some cool editing tools to mess around with in DALL·E, Stable Diffusion, MidJourney, Adobe Firefly and Craiyon like inpainting or variation that for learning purpose.

This can be practically applied to things like education. For instance, you can use it to create illustrations for biology or history.

It's useful for marketing, too. You can make product visuals.

Folks who do design work are able to use it to create poster or cover art.

There's some usefulness for research as well. You can use it to build data visualizations, for research projects.

There are some problems with these tools. For instance, people need to consider who owns the things they use such as pictures and music.

The tools can also be unfair. Have wrong information.

Then you have something like deepfakes that're a big issue.

Learners should be using these tools, and thinking about what they are doing with them Ethical considerations like copyright Bias Inaccuracies Misinformation hazards, such deep fakes.

The thing about computers working to make logos is that it makes making a brand seem pretty easy.

That computer system can whip up various takes of a logo in no time flat based on concepts that are uniquely industry relevant.

This allows companies and students to determine what looks good for their brand identity — and what doesn't.

Then, that computer system for making logos is pretty handy if you are someone who wants to see what the face of your brand could be too.

\* Infographic generation tools do a lot of the work for you. They help with the layout. Picking the right icons and colors. This means you can present your data and stories in an engaging way. You do not need to be a designer to use infographic generation tools. Infographic generation tools make it easy for users to make their data and stories look good.

\* Sketch to render tools are really cool because they can take a drawing that you do by hand and turn it into something that looks really real or has a special style. This is very helpful for people like architects and product designers and artists because it lets them try out their ideas quickly. Sketch to render tools are great, for sketch to render work and make it easy to see what something will look like before it is actually made.

\* The thing about intelligence based 3D modeling is that it can generate mesh models directly from text or 2D images. This makes it really easy for people to make prototypes and visualize things. Intelligence based 3D modeling is useful for students in education people who make games and engineers. It helps them to see what they are making and to try out ideas. Intelligence based 3D modeling is a big help because it makes prototyping and visualization accessible to learners, in education, gaming and engineering.

\* We can create a cool 3D world that feels real. This is called a 3D environment. We can use this to make landscapes and interactive spaces. These spaces can be used for gaming and virtual reality simulations. They can also be used for walkthroughs. This means we can walk through a building that has not been built yet. We can even use this to rebuild places and see what they looked like a long time ago. This is called reconstruction. We can use 3D environment creation to make all these things. Immersive 3D environment creation is an useful tool.

\* These visual and 3D Artificial Intelligence tools make it possible for anyone to be creative. They give people who're not experts the ability to make things that look very professional. At the time these Artificial Intelligence tools are also causing people to think about some important issues. These issues include what it means to be original who should get credit for creating something and how to use these Artificial Intelligence tools in a way. The use of Artificial Intelligence tools is making people think about these things.

Historians use AI to recreate “Roman city streets as they may have looked in the first century.” While speculative, these visuals aid in teaching and exhibitions.

## 5.2 Key Terms

GAN (Generative Adversarial Network) – An AI model that uses competition between a generator and discriminator to generate realistic images.

Zero-Shot Text-to-Image Generation – A model that dissipates random noise and colors into structured images following text inputs.

Prompt Engineering – The arts of crafting fine tuned prompts to govern the outcome from AI.

Inpainting – Modifying or replacing sections in an image with AI.

Logo Creation – Designing brand icons from descriptive cues using AI-generated tools.

Infographic Automation - Automate the production of data charts, layouts, and icons using AI for easy communication.

Sketch-to-Render – Rendering rough hand drawn sketches into polished images or renders via AI.

Immersive Environment AI generated 3D spaces, that can be experienced in a game, simulation or VR.

## 5.3 Descriptive Questions

What is the fundamental difference between GAN and diffusion model in image generation?

How does the granularity of an input prompt affect the pattern quality?

Give two instances where AI generated images can be used in education.

What ethical implications are there for using AI to produce photo-realistic images?

How does AI based logo designing help startups and students working on projects for brand identity?

How does sketch-to-render work and can you provide an example or scenario of professional usage.

What are the benefits of using AI powered 3D modeling tools in sectors like gaming and engineering?

In what ways might AI-generated immersive environments enrich learning about history or architecture?

5. A

## 5.5 Case Study

### Harnessing AI for Image Generation and 3D Visual Tools in Education and Design

- Artificial intelligence is changing the way we make pictures and models. We used to do it by hand. Now we can use computers to do it for us. Schools, companies and people who make things are using intelligence to make pictures, logos and other things.

They use intelligence for many things, including making pictures creating brands making infographics and building prototypes. They even use it to make reality worlds. This is a story, about how one school used intelligence to make pictures and models. The school wanted to make it easier for students to learn and be creative. Artificial intelligence is helping the students learn things and be more creative. The school is using intelligence to give students the best possible education. Artificial intelligence is really helping the students and the school.

#### Background

The lab wanted to fix three problems. The first problem was that designing things by hand took a time. The second problem was that many students were not very good at designing things. The third problem was that the lab did not have resources for making really cool 3D models and virtual reality worlds. Even though the lab had the design computer programs making things like logos, pictures, with information sketches of buildings and 3D models took a lot of time and special skills. The lab had to find a way to make these projects easier and faster to do. The lab needs to make content that people want to look at and simulations that feel real. So they started using intelligence tools, like DALL·E, MidJourney, Stable Diffusion, Adobe Firefly, Canva Magic Design and NVIDIA Omniverse. These AI tools help the lab design things faster. Make it easier for people to be creative. The lab uses these tools, including DALL·E, MidJourney and NVIDIA Omniverse to make this happen.

#### Problem 1: Time-Consuming Image Creation

Students and instructors usually spent a lot of time making visuals for reports, presentations or course materials. This held up projects and students and instructors did not focus much on the main ideas of the course materials. Students and instructors had to spend hours on this, which was not very helpful, for learning and teaching.

#### Solution:

The lab had a cool tool that used artificial intelligence to make pictures from what the students typed. For example they could type something like "A illustration of the solar system for high school learners" or "A futuristic city skyline, in watercolor style" and the artificial intelligence image generation tools would make a picture of it. The students got to see the pictures they made within a minutes.

The lab wanted the students to make the pictures better by typing things and trying again. This way the pictures would look nicer. The students would learn how to use the artificial intelligence image generation tools to get what they want. The students learned how to make the artificial intelligence image generation tools do what they wanted by trying things and that is what the lab was trying to teach them about the artificial intelligence image generation tools.

#### Problem 2: Difficulty in Communicating Complex Data

Research teams had a time showing people the results of their surveys and science information in a way that was interesting to look at. The old way of making pictures with information called infographics needed people who were good at designing and most students were not good, at this. Solution:

The lab started using tools like Piktochart and Canva to make pictures with information. The people doing the research would put in the information and tell the tools what to do such as "Make a picture that shows how climate change is affecting the earth: temperatures are going up ice is melting and the sea is rising." Then the tools would make looking pictures with symbols and different colors for each part. This made it easy to turn hard to understand information into pictures that're easy to look at and understand. The researchers used these tools to make pictures, about climate change.

### Problem 3: Limited Access to 3D Modeling and Immersive Environments

Students who are studying architecture, gaming and design have a time learning advanced 3D modeling. This is because they do not have the skills they need and they do not have a lot of time.

Creating cool environments that feel real is especially hard to do because it takes a lot of resources.

Solution:

The lab tried out some AI tools like Point-E, Luma AI and NVIDIA Omniverse. They found that even a basic request like "can you make a 3D model of an eco- house with solar panels and a garden" would give them something they could actually use.

The AI tools could make mesh files from this.

The lab also used these AI tools to make cool environments that people could walk around in. For example students who were studying history could explore what the streets of Ancient Rome were like with the markets and the amphitheaters and everything. This really helped the students learn by being, in the environment of Ancient Rome.

### Reflective Questions

1. How can AI-generated visuals balance creativity and originality in academic projects?
2. What problems can happen when students use Artificial Intelligence to make quality designs? This is something to think about because students are using Artificial Intelligence to make quality designs. We need to consider what ethical issues are related to students using Artificial Intelligence for creating quality designs. When students rely on Artificial Intelligence for creating quality designs there are some ethical issues that may arise.
3. So what are some ways that immersive Artificial Intelligence environments can change the way we learn in a classroom setting with Artificial Intelligence environments? Immersive Artificial Intelligence environments can really transform traditional classroom learning in ways with the help of Artificial Intelligence environments. For example Artificial Intelligence environments can make learning a lot fun and interactive, with Artificial Intelligence environments.

By integrating AI image generation, infographic tools, sketch-to-render systems, and 3D modeling platforms, the lab successfully addressed time, skill, and resource challenges. Students gained hands-on exposure to next-generation creative technologies, while educators could focus on higher-order teaching and analysis. This case demonstrates how AI democratizes design, empowering learners to engage in visual communication and immersive experiences that were once accessible only to experts.

5,579 Words

30,560 Characters

## \*% detected as AI

AI detection includes the possibility of false positives. Although some text in this submission is likely AI generated, scores below the 20% threshold are not surfaced because they have a higher likelihood of false positives.

### Caution: Review required.

It is essential to understand the limitations of AI detection before making decisions about a student's work. We encourage you to learn more about Turnitin's AI detection capabilities before using the tool.

### Disclaimer

Our AI writing assessment is designed to help educators identify text that might be prepared by a generative AI tool. Our AI writing assessment may not always be accurate (i.e., our AI models may produce either false positive results or false negative results), so it should not be used as the sole basis for adverse actions against a student. It takes further scrutiny and human judgment in conjunction with an organization's application of its specific academic policies to determine whether any academic misconduct has occurred.

## Frequently Asked Questions

### How should I interpret Turnitin's AI writing percentage and false positives?

The percentage shown in the AI writing report is the amount of qualifying text within the submission that Turnitin's AI writing detection model determines was either likely AI-generated text from a large-language model or likely AI-generated text that was likely revised using an AI paraphrase tool or word spinner.

False positives (incorrectly flagging human-written text as AI-generated) are a possibility in AI models.

AI detection scores under 20%, which we do not surface in new reports, have a higher likelihood of false positives. To reduce the likelihood of misinterpretation, no score or highlights are attributed and are indicated with an asterisk in the report (\*%).

The AI writing percentage should not be the sole basis to determine whether misconduct has occurred. The reviewer/instructor should use the percentage as a means to start a formative conversation with their student and/or use it to examine the submitted assignment in accordance with their school's policies.

### What does 'qualifying text' mean?

Our model only processes qualifying text in the form of long-form writing. Long-form writing means individual sentences contained in paragraphs that make up a longer piece of written work, such as an essay, a dissertation, or an article, etc. Qualifying text that has been determined to be likely AI-generated will be highlighted in cyan in the submission, and likely AI-generated and then likely AI-paraphrased will be highlighted purple.

Non-qualifying text, such as bullet points, annotated bibliographies, etc., will not be processed and can create disparity between the submission highlights and the percentage shown.

## Unit 5: Audio & Video Tools

### Learning Objectives:

1. Discuss about AI-generated audio and video basics and their importance in content generation.
2. Explain the organization and elements of well-formed prompts for audio and video writing tools.
3. Prove skilled hands-on ability to create AI-driven audio content through voice, sounds and music tools.
4. Try using video generation methods to get short videos that include image-to-video and text-to-video.
5. Assess multiple AI tools that can produce rich multimedia.
6. Implement audio and video production techniques in real-world contexts such as sales, education, and storytelling.

### Content

- 5.1 What is Audio Generation
- 5.2 What is Video Generation
- 5.3 Summary
- 5.4 Key Terms
- 5.5 Descriptive Questions

## 5.0 Introductory Caselet

### “When Silence Needs a Voice — Tanvi at StoryLine Studios”

Tanvi, a media production student, had always loved storytelling through film and animation. During her internship at **StoryLine Studios**, she was given a challenging task: produce a short teaser for a non-profit’s campaign — within 48 hours and on a limited budget. The concept was ready, and visuals were in place, but the team lacked voiceover artists and background music.

With little time to coordinate external talent, Tanvi decided to explore AI-based audio tools. She wrote a prompt for the voiceover:

“Narrate in a warm, empathetic female voice: ‘Every child deserves a future. Help us bring that future closer.’”

The result sounded professional. She adjusted pitch, tone, and pace through simple prompt tweaks. Next, she used an AI music generator to produce ambient background music tailored to the mood of the video. Within hours, the teaser was complete — with AI-generated voice and sound that resonated emotionally.

Encouraged by this success, Tanvi explored AI video tools next. For a separate assignment, she used an image-to-video generator to animate a product showcase with dynamic transitions and motion effects, all guided by simple prompt instructions. What would normally take a day in a video editing suite, now took her less than an hour.

Tanvi realized that audio and video generation tools, when used effectively, could dramatically reduce production time, lower costs, and enhance creative experimentation.

### Critical Thinking Question:

If you were Tanvi, how would you explain to a traditional filmmaker that AI-generated audio and video aren’t shortcuts, but tools that expand accessibility and creative control for small teams or solo creators?

## 5.1 What is Audio Generation

### 5.1.1 What is Audio Generation

Audio generation is a subfield of artificial intelligence concerned with the use of models to generate sound, music, speech and other audio signals. Contrary to conventional sound recording or manual composition and mixing of sounds, AI-based audio generation produces totally new audio from textual descriptions or input samples or structured parameters. The techniques include One used algorithms ultimately trained on of speech, environmental sounds and music recordings to get models to mimic human voice, produce tunes or make lifelike background noise.

Audio generation has come a long way in the last 10 years. Prior to this, sound synthesis was rule-based and implemented as digital signal processing: sounds were created based on mathematical formulas. For example, early TTS systems generated robot-like voices devoid of natural prosody. You'd also end up with a really synthetic sounding and simplified tone that was quite commonly found in older generations of sound generators.

Current progress is mainly led by deep learning. Systems such as WaveNet (by DeepMind), Tacotron (Google) and diffusion-based audio synthesizers are able to synthesize speech and music that share the same tone, rhythm and emotion found in human recordings. For instance, WaveNet proposed a neural model that generates raw audio waveforms one sample at a time as it sounds like real human voices. In music, tools like OpenAI's Jukebox or Suno AI can produce entire songs with accompanying instrumental backing and lyrics in a variety of genres.

#### Examples:

- The task of producing a new composition is given in natural language, for example “Generate 30 seconds of calming piano music suitable for meditation,” and an AI tool immediately generates the desired piece of music.

item “Turn this text into an enthusiastic female voice, American accent.”

and the AI generates speech with realistic pitch fluctuations.

Audio generation extends beyond entertainment. It is employed in accessibility (authoring audio for visually impaired people), education (creating narrated learning materials), business (producing e-learning resources) and research/science (light simulation of acoustic environments). It's thus one of the most general applications of AI in creative and practical space.

“The AI model WaveNet does not store audio recordings of words or phrases. Instead, it creates audio by predicting one sample of a sound wave at a time — 24,000 samples per second in some cases — which makes its speech “barely discernible from human voice.”

## 5.1.2 Prompt Structure for Audio Gen AI Models and Tools

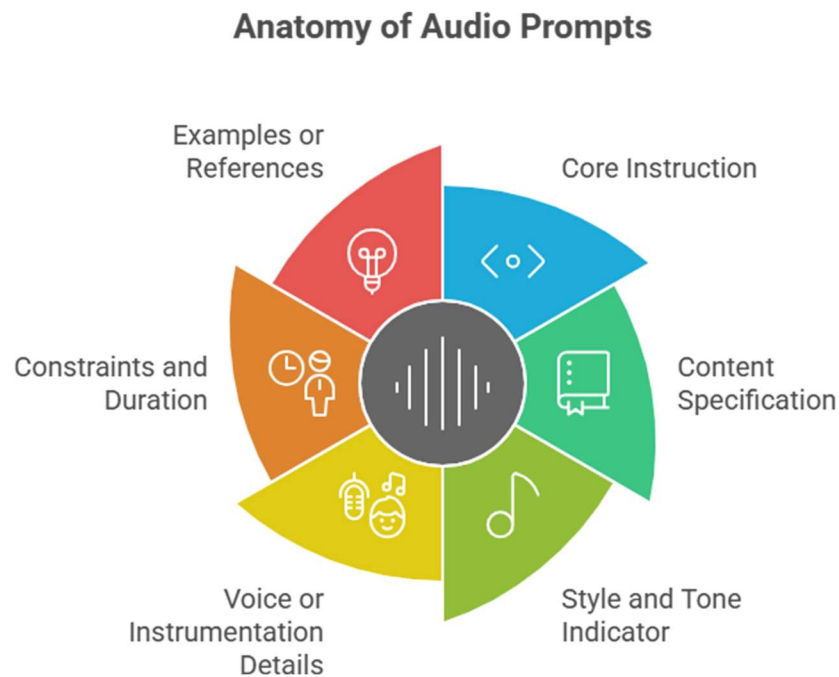

figure: **Key Components of Audio Prompts**

As with text and images, prompts form the basis for audio content generation. A prompt is the input command — text, image or a combination of both — that instructs the AI in making sound. The contents and clearness of the prompt are directly affecting the quality, style and context of the produced audio.

### Key Components of Audio Prompts

#### Core Instruction

Describes what the audio is mostly about.

- o Example: “Produce a male voice to read this script.”
- o Example: “Write an electronic dance track with positive vibes (upbeat).”

#### Content Specification

In the case of speech, this is the text that will be spoken. For music it may be the theme, the lyrics, even just the mood.

- o Example (speech): “Hello, so glad to see you at our session on climate change today.”

- o Example (music): “A jazzy tune with saxophone and relaxed drums”

### Style and Tone Indicators

Style refers to emotional or genre-based attributes.

- o Example: “Tell this story in a way that it is dramatic and with suspenseful breaks.”

- o For example, “Create classical piano music – calm, reflective”

### Voice or Instrumentation Details

For speech: the voice gender, aging, accent or pitch. For music: indicate instruments and/or an arrangement.

- o Example: “British female voice, middle aged, formal tone.”

- o E.g. ‘orchestral arrangement with violins, trumpets and drums’ .

### Constraints and Duration

The user may specify length, tempo or technical features.

- o For example, “30 second podcast intro up-beat background music.”

- o Example: “Generate your speech in less than a minute, clear and professional.”

### Examples or References

Some tools allow reference inputs.

- o E.g. allowing the user to upload a voice clip and then ask for “this paragraph in this voice” style.”

- o Example: Contribution of a short melody that could be developed into a complete song.

### Types of Audio Prompts

- Speech Prompts – Text-to-speech prompts.
- Music Prompts- Descriptions based on genres, moods and instruments.
- Hybrid Prompts - Use printed text + voice or melody uploads to refine your input.

### Importance of Iteration

Generation can benefit from several iterations of a prompt. For example:

- First prompt: “I want you to make serene background music.”
- Pristine prompt: “Make some peaceful background piano music, slow tempo, for meditation.”
- The last of the prompts: “Fill 60 seconds with gentle background piano music in a slow tempo, supported by soft strings.”

This is akin to the way in which human creators work –they iterate on drafts until they arrive at the finished product that meets expectations.

### 5.1.3 Hands on to Audio Generation AI Tools

Which audio generation tool should I use?

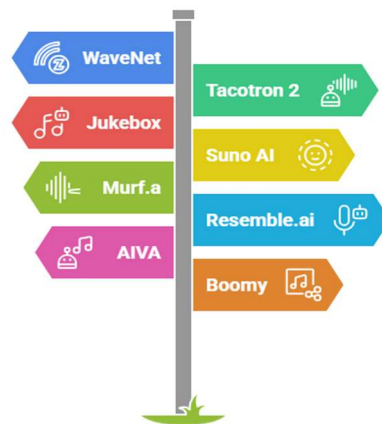

figure: Popular Audio Generation Tool

1. Real-world musical tooling experience allows students to understand the limits of the creative and technical. By playing with a variety of platforms, students and pros can learn how their prompts affect the outcome, what to do with audio on real projects and that ethical quandaries could arise.
2. Famous) Audio Building Apps/utilityUnity; Incremental result typesSeveral years - multiple learning objectives-inyearsAlpha; Years and assetIntro GameDev; In last lessonHotz Software Solutionssome extensionsVisualWorksStanimirov, Kostadin MDichotomyLL f(;:=[ ]).1004welcindex\_shtmlgodunov codeLabVIEW hotkeys NTNU Popular\*\*GenerationofAudioTools
3. WaveNet (DeepMind) – Generates human-like speech for TTS systems.
4. Tacotron 2 (Google) – A version of Tacotron which can be trained without guidance data via unsupervised training on a large corpus.
5. Jukebox (OpenAI) – Create music with lyrics in various genres.
6. Suno AI – Tailored for music composition with generative lyrics and melody.
7. Murf. ai - Makes a real sounding voiceovers for corporate, training and marketing.
8. Resemble. ai – Clone any voice for speech applications.
9. AIVA – Artificial Intelligence Virtual Artist, which composes classical music and soundtracks for films or games.
10. Boomy – Lets users make and publish original songs in a matter of minutes.

## Hands-on Exploration Activities

### · Speech Production Practice:

Students can feed the very same text into a few TTS tools (e.g., Murf. ai vs. Tacotron) then you can compare the accents, tones and pacing. And this is an example showing that models receive different explanations about style.

### · Music Generation Activity:

Students can with Boomy make a short track by typing in the mood as “happy, upbeat, fast tempo.” They then modify the prompt to “calm, reflective, slow tempo with acoustic guitar” and wait for stylistic effects.

### · Voice Cloning Investigation:

Using tools like Resemble. ai, participants submit a brief recording of their own voice and then receive an audio output reading a text. This is one example of how AI can mimic individual vocal nuances.”

## Applications of Audio Generation

### Education

- o Courses in form of spoken or narrated lessons for e-learning platforms.
- o Automatically generate audiobooks from textbooks.

### Accessibility

- o Text-to-speech tools to let people who are visually impaired listen to written content.
- o Instant translation into spoken language for inclusive conversation.

### Business and Marketing

- o Voiceovers – commercials, training videos, presentations.
- o Custom music for brand campaigns.

## Entertainment and Creativity

- o Writing Songs with other musicians.
- o Live soundtracking for video games or film.

## Research and Simulation

- o Development of artificial voices for psychological experiments.
- o The simulation of ambient sounds in scientific visualization.

## Ethical and Practical Considerations

Audio generation provides exciting possibilities, but also poses challenges:

- Authenticity: Cloned voices could be abused for identity fraud or misinformation.
- Copyright Problems: AI-generated music can sound too much like a track in training data.
- Bias: The speech generation models generated can carry accent or gender bias from the data.
- Transparency: AI-generated audio must be identified to the listener to prevent being mistaken for a human.

Example of Issue: In the past few years, AI-generated voice deepfakes have been employed in mimicry of political figures, prompting us to question security and trust issues. This underscores the importance of checks and balances on the use cases for audio synthesis.

## Learning Through Practice

Tactical skills, as well as the ability for critical thinking, are cultivated through hands-on experiences. For example, a classroom activity might be:

- Instructing an AI tool to create a voiceover for a science video.
- Biaising outputs in various tones: formal, informal and motivational.
- Everything about how tone changes the structured educational effect of that content.

Through such activities, students develop functional literacy in the use of sound generation.

### “Activity”

Imagine a message of 100 words about how the photosynthesis takes place. Blend in any generator of audio (e.g Murf. ai, Resemble. ai, or Tacotron).

- Start the script in the non sexed-up version of a female voice.
- Now, also write that very same script with identical feeling this time in a MALE voice.
- Consider comparing the two outputs for clarity, emotional engagement, and usefulness for learning.

Write a brief reflection (200 to 250 words) about the way voice style, tone and gender shaped your reaction to the narration.

**Knowledge Check 1**

Choose the correct option:

1. Which of the following best describes video generation?
  - a) The manual process of filming live-action videos with cameras
  - b) The use of AI models to synthesize moving images from text, images, or hybrid prompts
  - c) The process of editing pre-recorded footage with special effects
  - d) The conversion of audio files into subtitles
2. Which element of a video prompt specifies how the scene is framed or moves?
  - a) Style indicator
  - b) Camera movements and perspective
  - c) Duration and format
  - d) Core instruction
3. Which of the following tools is primarily used for generating professional AI avatar-led video presentations?
  - a) Runway Gen-2
  - b) Pika Labs
  - c) Synthesia
  - d) Kaiber AI
4. What is a key advantage of image-to-video AI tools?
  - a) They replace all traditional video production methods
  - b) They animate static images into dynamic sequences
  - c) They generate only audio tracks from images
  - d) They cannot apply stylistic changes to outputs
5. Which of the following is a major ethical risk associated with AI video generation?
  - a) Slow production cycles
  - b) Overuse of manual labor
  - c) Creation of deepfakes and misinformation

d) Limited ability to produce marketing content

## 5.2 What is Video Generation

### 5.2.1 What is Video Generation

Video generation: It is used to create dynamic moving images with the help of artificial intelligence (AI) models and other computational tools, as opposed to traditional filming or manual animation. Compared to traditional approaches that require video cameras, actors or animation expertise, AI-based video generation creates full-length sequences of videos based on text prompts, still images or short clips. This is basically the marriage of computer vision, natural language processing and generative modelling.

The field gained momentum with advances in deep learning, particularly generative adversarial networks (GANs), and diffusion-based architectures. Although early attempts resulted in blurry or nonsensical outputs, current models generate crisp videos that are visually and contextually consistent, yet stylistically varied.

Examples of Video Generation Applications:

- A filmmaker instructs an AI tool: “Produce a brief moment showing a sunset over the ocean with seagulls flying.”

In just a few minutes, the system generates a natural scene in motion.

- A marketer types in: “Make a 15-second promo video of a car that resembles it travels through a neon city.” The AI paints out smooth video frames that look like you describe.

- An educator offers: “Quick and easy animated explanation of the water cycle for middle school students.” The AI generates a brief educational video with voiceover and graphics.

Video creation is no longer confined to entertainment and academia. It can be used in advertisement rapid prototype, innovative and creative storytelling in the power of visual simulation; products show round, personalise communications (such as avatars make become/have access to Message). This has made it a disruptive technology that is changing the way people and businesses think about creating video content.

#### Did You Know?

“State-of-the-art models of the type proposed here are trained on billions of images and attributed motion, and can interpolate motion between frames. This means a single still image of a dog can be animated into a clip showing the dog running, even though the AI has never “seen” that exact movement before.”

### 5.0.1 Structure of the prompt for VGAI Models and tools

Like text, image and audio generation, video generation heavily relies on the design of prompts. The video prompt

gives the system text instructions, images or combined input that provides details about the content, movement, style and duration of a video. Clearer prompts lead to more accurate and informative outputs.

## Key Components of Video Prompts

### Core Instruction

Describes the primary focus of the article or event.

- o Example: A “cat jumping on a sofa.”
- o Example: “A city at night and fireworks.”

### Detail and Context

There is much richness to be gained by adding descriptive context that is more realistic.

- o E.g: “A fluffy orange cat jumps on a grey leather sofa in a modern living room.”

Guides the system to a certain style.

- o Sample: “Cartoon animation style with the use of bright colors.”
- o e.g. "Theater style with dramatic lighting."

### Camera Movements and Perspective

Describes how the scene is framed or shot.

- o e.g., “Capped angle view with slow pivot.”
- o or Ex: “Walking through a forest in first-person perspective.

### Duration and Format

BM Assures compatibility with the given use of the video.

- o Example: “Create a 10-second piece of footage at 1080p.”
- o Normal Example: "5-Second GIF Loop"

### Reference Inputs

Some resources even have a starting image or video to start with.

- o Example: Submitting a still photo of a landscape with the prompt: “Make this scene move with motion controllers.  
clouds and flowing river.”

## Types of Prompts

- Text-to-Video Prompts: Purely text-based descriptions.
- Image-to-Video Prompts: Animating a static image into a moving sequence.
- Hybrid Prompts: Combining text, image, and sometimes audio inputs for enhanced control.

## Importance of Iteration

When you are working with video outputs they usually need to be improved. You have to do this by asking for changes over again until you get what you want from the video outputs. This process can be a bit frustrating. It is necessary to make the video outputs better.

- First attempt: “A dog running in a park.”
- This is a picture of a retriever. The golden retriever is running across a park. There are children playing in the background of the retriever scene. The golden retriever and the children are having a time, in the park.

cinematic style, 15 seconds.”

- Final: “A golden retriever running across a grassy park with children in the background, cinematic style, slow-motion camera effect, 15 seconds, 1080p.”

Iteration improves not only realism but also alignment with specific project requirements.

## Hands on to Video & Image to Video AI Tools

Practical engagement with video generation platforms allows learners to grasp how prompts translate into visuals, understand tool limitations, and discover applications in different domains.

## Popular Video Generation Tools

### Runway Gen-2

A popular text-to-video model.

Ex.: The user writes “A paper airplane flying through a classroom.” The tool creates a plausible 4- second video.

### Pika Labs

Focused on short videos of artistic nature and also film like.

For example: “A knight strolling through a foggy forest in fantasy.”

### Synthesisia

Specialised in AI avatars & business video presentations.

Example: Avatar presents corporate training content in various languages.

### Kaiber AI

Converts Still images to videos.

Example: Submit the art of a band and animate it so that becomes a music video.

### Stable Video Diffusion

Generalizes diffusion processes to video, for realistic animation.

Example: Create brief video responses from text and image sources.

### DeepBrain AI

Develops hyper-realistic AI avatars for news, e-learning or customer communication.

### Google Veo

, an advanced video generation model developed by Google DeepMind for high-quality (and cinematic-style) video generation.

Example: A prompt such as “A timelapse of a city skyline during sunset in 4K resolution” will result in video segments with lush visuals and fluidly animated sequences with realistic motion and lighting.

### Kling by Kuaishou

A state-of-the-art model that excels in temporal consistency and photorealism of AI-synthesized videos.

Frequently compared to Sora and Veo.

For instance, for a prompt such as “a surfer riding a giant wave at golden hour,” the outputs include significantly detailed and smooth motion video.

### Krea AI

Specialized in real-time video and image production (dynamic motion effects, commonly used for visual designers, on social media or specific content.)

Example: Create a looping motion design around the prompt “neon particles form galaxy in slow-mo”

## Hands-on Exploration

### Text-to-Video Experiment

Learners enter prompts like “A busy night time street scene in Tokyo, cinematic style, 5 seconds.” They can later improve prompts by modifying style (e.g. cartoon or realistic), duration, or camera angles. Comparing results shows how small tweaks influence the outcome.

### Image-to-Video Conversion

Students upload an image — say, a photo of a beach — and they would add: “Animate the waves. seagulls.” See how the tool turns static objects to life, a creative metamorphosis it can make!

### Educational Video Generation

A teacher or a student might type: “Create a 30-second animated explanation of photosynthesis.” The AI produces a narrated video with changing images as an education tool.

### Business and Marketing Use

Marketers will be able to make product demos with calls like “Show me a rotating 3D animation of a smartwatch and, oh yeah, also picture what this watch face design would look like on my own wrist.”

glowing display.” The set of tools creates video assets that can be output to cut down on production timelines.

### Applications of Video Generation

#### Education

- o Animation-based study modules.
- o Video reviews of textbooks.

#### Entertainment

- o Short film prototyping.
- o Visualize storyboards for Films.

#### Marketing and Business

- o Video promotion and advertising.
- o Custom built, avatar-driven customer support videos.

#### Research and Simulation

- o Training in realistic scenarios through manipulation.
- o Visualization of dynamic scientific data.

#### Ethical and Practical Considerations

- Misinformation: AI-led videos can be used to make deepfakes.
- Copyright: Generated works might also show similarity to dataset samples used in training.
- Bias and Representation: AI users can be biased if the avatars which represent them are not carefully controlled.
- Transparency: Viewers should be notified when video content is created by AI.

Sample Worry: AI-generated political ads with fictional scenes could deceive viewers, underscoring the desperate need for guidelines and verification systems.

## Learning Through Practice

Digital and physical video production experiences drive curiosity, discovery, design-thinking, ethics and creative-reuse. Possible class Organization: A possible classroom organization could be:

- Producing a brief animated clip in Runway Gen-2.
- Refining prompts to contrast stylistic variations.
- Composing a brief personal reflection on educational and professional implications, including ethical considerations.

With these activities, they can transform themselves from passive watchers to active producers for the latest AI technology.

## 5.3 Summary

\* Audio generation is what happens when we use Artificial Intelligence and deep learning models to make speech,

music and sound effects from text, parameters or samples. We are talking about audio generation. It is really interesting. Audio generation is, like a tool that helps us create sounds.

\* on people used rules to create sounds with computers and this resulted in sounds that were not very natural.

These sounds were of robotic.

Now we have new ways of doing things with computers like WaveNet and Tacotron and other systems that use something called diffusion.

These modern systems can generate speech that sounds like a real person is talking and music that is really complex and interesting.

The music and speech generated by these systems, like WaveNet and Tacotron sound very natural.

\* Applications of audio generation are really cool. Audio generation is used for accessibility. This means it helps people who're visually impaired by turning text into speech that they can hear.

Audio generation is also used in education. For example it is used to create lessons and audiobooks.

Audio generation is used in business too. It is used to create voiceovers and training modules.

We also use generation, for entertainment. Audio generation is used to create songs and soundtracks.

Audio generation is even used in research. It is used to create environments. Audio generation is an useful thing.

\* Prompts are really important for making sound good.

The prompts need to be clear and have a lot of details.

They also need to have a style to them.

This is what makes the speech or music sound quality.

For example the input can say what tone to use or what accent to have.

It can also say what instrument to use or how long the music should be.

Sometimes people even give a sample of a voice or music to copy.

This is used for things like making a copy of someones voice or making music.

The inputs for voice cloning or musical composition can be very specific.

They can include things like the tone or the accent or the instrument.

This helps the audio sound real and nice to listen to.

The prompts for generation are, like a guide.

They tell the system what to do and how to make the audio sound good.

This is why prompts are central to generation.

\* Iterative prompting is really important. This is because when you refine the instructions a little at a time you get outputs that are more accurate and make sense in the context of the iterative prompting. The iterative prompting helps to get results.

\* Popular tools for generation include WaveNet, Tacotron, Jukebox, Suno AI, AIVA, Murf.ai and Boomy. These audio generation tools are really useful. WaveNet is one of these audio generation tools. Each of these audio generation tools like WaveNet, Tacotron, Jukebox, Suno AI, AIVA, Murf.ai and Boomy serves areas. For example some of these audio generation tools are used for speech. Some audio generation tools are used for music composition. Then there are audio generation tools used for voice cloning. Audio generation tools, like WaveNet, Tacotron, Jukebox, Suno AI, AIVA, Murf.ai and Boomy are very helpful.

\* The thing about voices is that they can be used in bad ways like pretending to be someone else.

This is a problem.

Cloned voices can also cause issues with music because of copyright rules.

Then there is the problem of biases when computers generate speech.

We need to make sure people know when they are listening to audio that was made by a computer.

This is really important, for voices and other audio made by artificial intelligence.

Transparency is necessary when it comes to labeling audio that is generated by intelligence like cloned voices.

\* Video generation is, about making videos from scratch. It uses intelligence to create video clips that move and change. The artificial intelligence takes information from text, pictures or a mix of both. This means you do not need to use a camera to film something or draw each picture by hand to make a video. Video generation makes it all happen automatically.

\* GANs and diffusion-based architectures made it possible to create good videos.

These videos can look real or have a special style.

The best part is that algorithms can make these videos by themselves.

GANs and diffusion-based architectures are the reason we can have great videos now.

\* When you want to make a video you have to give some details about what you want in the video. This includes what the video is about what style it should be, in how long it should be and what the camera should show. Sometimes you also give pictures to help make the animation.

You have to try a times to get the video just right so you do it again and again until it is accurate and looks good. This is called iteration and it helps make sure the video is what you wanted the video generation is done with the style and the right details.

\* Video generation is really useful in areas.

Video generation is used in education to make lessons.

This makes learning fun for students.

Video generation is also used in entertainment for film prototyping.

People use video generation in marketing to make product demos and promotional ads.

Video generation is used in research to make simulations.

Video generation is very helpful, in all these areas.

\* Video generation tools like Runway Gen-2 and Pika Labs and Synthesia and Kaiber AI and Stable Video Diffusion and DeepBrain AI are really helpful.

These video generation tools allow people to make videos from text or images.

You can also add your avatars or animation or cinematic effects to the videos made with video generation tools like Runway Gen-2 and video generation tools like Pika Labs.

Video generation tools such, as Synthesia and Kaiber AI and Stable Video Diffusion and DeepBrain AI make it easy to create videos with the help of text or images. You can customize the videos with avatars or animation or cinematic effects using video generation tools.

\* Practical exercises in video generation are really helpful for people who want to learn. These exercises teach learners, about designing prompts and exploring their creativity. They also learn how audio and video generation tools work. At the time learners think about the ethical responsibilities that come with audio and video generation. This is a part of learning about audio and video generation.

Both technologies democratize creativity, giving students, educators, and professionals access to professional-quality outputs, but also highlight the need for digital literacy and critical evaluation of authenticity.

## 5.4 Key Terms

Audio Generation: using AI models to produce speech, music or sound effects.

WaveNet – A DeepMind neural network for producing raw audio waveforms with the human-like intonation.

Voice Cloning – Artificially copying a person’s voice using example audio.

AIVA – Composing classical music and film scores with the help of AI.

Video Generation – Movement graphics and clips generated by AI from text, images, or combination prompts.

Runway Gen-2 -- A text-to-video model that creates brief cinematic videos.

up Image Animation (in a form of Gif creation) from static images -Automated Video /Wizmotions : Wizmotions enables the animating of logos names and designs into moving video!

Synthesia – A video software which generates lifelike AI presenters giving presentations or speeches.

## 5.5 Descriptive Questions

- 6 How did models such as WaveNet and other neural network models bring audio generation systems beyond earlier rule based systems?
- 7 What are three things that make a good audio generation prompt?
- 8 Provide one educational use case and one business use case for AI-generated speech.
- 9 What are the ethical implications of AI voice cloning tech?
- 10 What is the role of diffusion models in contemporary video synthesis?
- 11 Discuss the use of camera angle and length when producing video prompts.
- 12 Contrast the text to video and image to video methods with example.
- 13 Why is it instrumental to iteratively prompt the network for both audio and video outputs?

2. B
3. C
4. B
5. C

## 13.1 Case Study

### Transforming Education and Business Communication through AI-Based Audio and Video Generation

3. The artificial intelligence thing has changed the way companies make and share audio and video content.

We used to need studios and equipment to do this and it would take a long time.

Now we can use tools that work with prompts to make speech, music and videos that move.

This story is about a company that teaches people things online and how they used intelligence to make audio and video to help more people make content faster and make learners more interested, in the artificial intelligence audio and video content.

## Background

The company had a time making a lot of educational content for people who learn in different ways and live in different places. They needed to make voiceovers for lessons and videos that explain things and this required professional people to speak, edit and animate which made everything take longer and cost money. The people who were learning wanted content that was really good for them and fun to watch. So the company started using computer programs like Murf.ai, AIVA, Jukebox, Runway Gen-2 and Synthesia to make things easier and faster and to get results, with educational content and these computer programs.

## Problem 1: Time-Consuming Voiceover Production

We had to record voices for hundreds of lessons. This meant we needed voice artists and we had to edit the recordings for a long time. This caused delays. Sometimes we made changes to the script and that meant the voice artists had to record the entire thing all over again.

## Solution:

The company used intelligence to make systems that can turn text into speech like WaveNet and Murf.ai. Teachers just had to write what they wanted to say and pick the kind of voice they wanted like the accent or the tone. They could make a lesson that's twenty minutes long in just a few minutes.. They could change how fast or how high the voice sounded right away. They could even make a copy of the teachers voice so it sounded the same in all the classes without having to go to a studio to record it again. This way the company could make all their classes sound the same which's good, for the brand. The company used voice cloning. It worked well with WaveNet and Murf.ai to make this happen.

## Problem 2: Limited Engagement with Static Learning Materials

People who are learning often lose interest when they see slides that are not moving and things that are a lot of text. This makes it harder for them to really get what is being said and remember it. When video is not used to help explain things it is even harder to understand things that're complicated. The video content is really important to help learners understand topics.

### Solution:

People used tools like Runway Gen-2 and Synthesia to make videos. These tools were really good at making videos. The teachers made requests like "Make a video that explains how photosynthesis works". They wanted the video to be thirty seconds long. Have a voice telling what is happening.

The tools made these videos with moving pictures, sounds and voices. For classes that people pay for they used avatars that could speak languages. This helped people from around the world understand the videos. The videos were available in languages because of these avatars. Runway Gen-2 and Synthesia were useful tools, for making these videos.

## Problem 3: High Costs of Marketing and Promotional Content

Creating promotional campaigns previously required agencies and expensive equipment. Producing multiple ad variations was both costly and time-intensive.

### Solution:

The marketing team used Kaiber AI and Pika Labs to make some clips. They tried out a things. For example they asked for a 15-second animation that shows a new AI-powered learning app. This is what they got. The results were really good. They got them in just a few hours.

This meant they could try out a few versions of the campaign. They could see which one people liked best.. The best part is that it did not cost a lot of money. They could do all these tests without spending much. The Kaiber AI and Pika Labs were a help, to the marketing team and the AI-powered learning app.

## Reflective Questions

Give one educational and one business application of AI-generated speech.

4. What ethical risks are associated with AI voice cloning technologies?
5. How do diffusion models contribute to modern video generation?
6. Explain the role of camera perspective and duration when designing video prompts.
7. Compare text-to-video and image-to-video approaches with suitable examples.
8. Why is iterative prompting essential in refining both audio and video outputs?

26,987 Characters

## \*% detected as AI

AI detection includes the possibility of false positives. Although some text in this submission is likely AI generated, scores below the 20% threshold are not surfaced because they have a higher likelihood of false positives.

### Caution: Review required.

It is essential to understand the limitations of AI detection before making decisions about a student's work. We encourage you to learn more about Turnitin's AI detection capabilities before using the tool.

### Disclaimer

Our AI writing assessment is designed to help educators identify text that might be prepared by a generative AI tool. Our AI writing assessment may not always be accurate (i.e., our AI models may produce either false positive results or false negative results), so it should not be used as the sole basis for adverse actions against a student. It takes further scrutiny and human judgment in conjunction with an organization's application of its specific academic policies to determine whether any academic misconduct has occurred.

## Frequently Asked Questions

### How should I interpret Turnitin's AI writing percentage and false positives?

The percentage shown in the AI writing report is the amount of qualifying text within the submission that Turnitin's AI writing detection model determines was either likely AI-generated text from a large-language model or likely AI-generated text that was likely revised using an AI paraphrase tool or word spinner.

False positives (incorrectly flagging human-written text as AI-generated) are a possibility in AI models.

AI detection scores under 20%, which we do not surface in new reports, have a higher likelihood of false positives. To reduce the likelihood of misinterpretation, no score or highlights are attributed and are indicated with an asterisk in the report (\*%).

The AI writing percentage should not be the sole basis to determine whether misconduct has occurred. The reviewer/instructor should use the percentage as a means to start a formative conversation with their student and/or use it to examine the submitted assignment in accordance with their school's policies.

### What does 'qualifying text' mean?

Our model only processes qualifying text in the form of long-form writing. Long-form writing means individual sentences contained in paragraphs that make up a longer piece of written work, such as an essay, a dissertation, or an article, etc. Qualifying text that has been determined to be likely AI-generated will be highlighted in cyan in the submission, and likely AI-generated and then likely AI-paraphrased will be highlighted purple.

Non-qualifying text, such as bullet points, annotated bibliographies, etc., will not be processed and can create disparity between the submission highlights and the percentage shown.

# Unit 6: AI Briefs & Projects

## Learning Objectives:

1. Create full AI briefs and brand-specific case studies using a range of AI tools and methods.
2. Perform advanced research and data analysis with LLMs & other AI-based tools to inform decision making.
3. Implement quick engineering solutions to build multi-modal AI solutions across text, image, audio and video.
4. Develop seamless content workflows across multiple modes for any purpose or branch.
5. Create convincing pitch decks and presentations with the help of AI-powered design & writing tools.
6. Blend multiple AI capabilities in an end-to-end solution for creative, business or technical projects.

- 1.1 Integration of Multiple AI Tools
- 1.2 Summary
- 1.3 Key Terms
- 1.4 Descriptive Questions
- 1.5 References
- 1.6 Case Study

## 6.0 Introductory Caselet

### “When One Tool Isn’t Enough — Ayaan at StratEdge Consulting”

Ayaan, a postgraduate student in management with an interest in digital strategy, scored an internship at StratEdge Consulting, a venture that helps young firms frame investor-ready business pitches. For his first big job he was tasked with creating an entire go-to-market presentation for a health-tech client who was beginning the release of a smart wearable device.

Rather than rely on old fashioned tools and personal data collection, Ayaan suggested a workflow that incorporates AI. In an initial step, he developed a competitor analysis and market gap with the use of an LLM. Next, he wrote an AI brief to direct text creation on the executive summary and problem-solution framing.

For spectacularity, Ayaan threw some concept visuals of the product being used into an AI image generator. He then used design tools powered by AI to create infographics for key data points and a brand palette. To make it sound more personal, he also created a synthetic voice-over of a 60-second teaser video of the pitch.

Text, image, video, data and presentation: Each step was empowered by diverse AI tools orchestrated through unified strategy. A task that would normally require five workers and one week of labor to finish, Ayaan completed in just three days.

His end product was not only visually sophisticated and strategically solid but showed how multiple AI systems could coexist to create an integrated, end-to-end solution.

Critical Thinking Question:

If you were Ayaan, how would you explain to someone who thinks a human doing a specialized work is the way to get good quality why one would need multiple AI tools in a project?

## 6.1 Integration of Multiple AI Tools

AI technology has quickly progressed from narrow, task-specific applications to cohesive environments where many tools act in concert to achieve complex results. Rather than leaning on a single AI model to create text, images, or audio data, modern workflows typically involve combinations of approaches. Such integration results in increased effectiveness, creativity, and problem solving potential for the fields of marketing, education, health care, research and entertainment.

Automation of end-to-end workflows is possible by integrating multiple AI tools in a single workflow. For example, in a brand campaign the use of large language model (LLM) can entail utilizing an LLM to generate strategic briefs, an image generation tool to produce campaign visuals, audio generation technology to create voiceovers and video generation technology for combining these into a coherent promo video. Integration is what's taking us away from siloed AI outputs at the application-level to end-to-end, multimodal solutions that are text-, vision-, audio-intensive and interactive.

### 6.1.1 Creating AI Briefs & Case Studies for Brands

In the branding and marketing industry, briefs/opportunity matrices and case studies are key mechanisms for strategy signals and client/consumer conversations. Historically, generating these documents has been a manual, laborious task that involved market analysis and feedback from ideation sessions comprising strategists, copywriters and designers. Multiple AI tools are now plugged into this process and that facilitates brands in building structured, rich and visually appealing materials much faster.

#### AI-Driven Brand Briefs

And in this context, think of a brand brief as simply a guiding document which lays out what are you trying to achieve, who is the target audience, what are the key messages and creative direction for campaign. This is where AI can play a role in multiple ways:

#### Initial Drafting Using LLMs

Big language models such as GPT or Claude can conceptualize structured drafts of brand briefs, inspired by user prompts.

o Example: A marketer enters, "Write a brand brief for new organic skincare product focused on

young professionals in urban areas."

Sections include brand vision, audience diversity, value propositions and recommended channels of communication.

#### Data-Driven Insights

And AI-equipped research tools can parse customer sentiment, competitor tactics and market trends. This helps to ensure the brief is rooted in evidence and not belief.

## Integration with Visual Tools

Models like MidJourney or DALL·E can generate moodboards or sample visuals that match the brief. This gives all involved parties the ability to see the campaign direction early.

## AI-Enhanced Case Studies

Case studies showcase how a brand addressed an issue, provided value, or experienced success. AI incorporations makes both creation and presentation efficient:

- **Drafting Text:** LLMs can write client stories with problem-solutionoutcome format which is appealing to the reader.
- **Graphic design:** A product like Canva's AI Designer can auto-magically create charts and infographics that did the math on all your performance metrics for you.
- **Video Embedding:** AI video tools could generate short testimonial clips or animated explanations, illustrating the written case study.

## Example in Practice:

**What Are the Goals of a Case Study?** A case study by a digital marketing agency that is creating for an e-commerce client could:

- Use GPT to write the text story behind why sales were up 40%.
- Use Stable Diffusion to create custom illustrations for customer journeys.
- Generate a data visualization with artificial intelligence summarizing campaign results.
- Use synthesia to create a short video of an AI avatar telling the success story.

This multi-tool collaboration results in more engaging, data-rich and compelling case studies for stakeholders.

### Did You Know?

“There are some AI tools that automatically create brand briefs by analyzing a company's social media presence and its customer reviews. These instruments reveal brand voice, audience demographics and even how competitors are positioned — content curation tasks that take some of the lifting off of strategists.”

## Research and Analysis Using LLMs & AI Tools

Both students and professionals use academic, business, or creative software. Combining LLMs with domain-specific AI applications, researchers are now able to not only retrieve information more rapidly, but also process and analyze it more effectively.

### Literature Review and Summarization

LLMs are particularly good at generating concise summaries of large bodies of text.

- Example: A scientist studying renewable energy can feed hundreds of academic papers into an algorithm-driven summarization system. Key conclusions are drawn and the LLM identifies research gaps and presents a comprehensive review, thus saving weeks of investigation work.

### Data Analysis and Visualization

AI itself can help analyze quantitative data and present results in a visual manner.

- Example: An economist may import a CSV file of economic data into an AI analysis system. The system creates trend graphs, correlation matrixes and natural language explanations of the discovered patterns.

- Visualization integration with Tableau or Power BI for even better understanding of the results so they can be understood by end and non-technical users.

### Sentiment and Trend Analysis

AI models, built on feeds derived from social media, surveys and customer reviews can measure public sentiment and recognise emerging trends.

Example: When a business releases a new drink it can listen to Twitter mentions and online reviews thanks to sentiment analysis tools. Combined with LLM generated reports, the manufacturer gains an enhanced understanding of customer sentiment.

### Integration of multi-modal AI promotes comprehensive research WF:

- LLMs are hypothesis generators.
- Image and video product authoring tools generate models or simulations as illustrations.
- Audio creation applications create findings with localized narratives for presentations.

### Case Illustration:

For example, an urban planning team who is analyzing traffic congestion may:

Apply LLMs for summarizing the existing literature regarding smart city traffic.

Use AI-based data analysis to analyze traffic data in real time.

Create AI-powered videos as part of Visual Simulations to show how proposed management measures would work in practice. This full integration enhances both the depth of analysis and the ease of communication.

### Did You Know?

LLMs are not only able to generate abridged text of long scientific papers, but also cross-reference research from several sources. For instance, after scanning over 50 articles on climate change, an LLM is able to bring out contradicting views thus aiding researchers in identifying those knowledge gaps faster than the status quo.”

### 6.1.2 Prompt Engineering for Multi-Modal Solutions

As AI ecosystems mature, one of the most important capabilities is prompt engineering: designing good prompts to steer many AI tools at once. The need for a text-based solution also means that consideration for consistency, coherence, and creativity must be so thoroughly designed into the prompt that it can seep out from words to images to sounds.

## The Role of Prompt Engineering in Multi-Modal AI

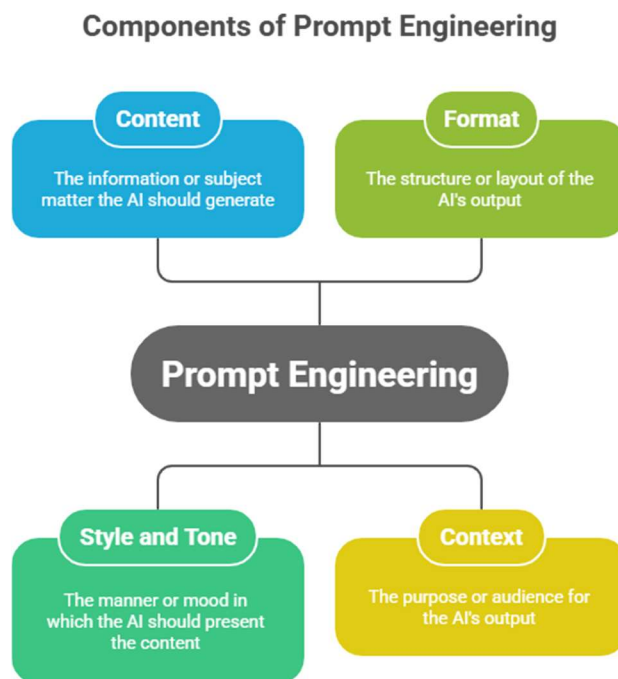

figure: **The Role of Prompt Engineering in Multi-Modal AI**

Quick engineering You write a very detailed, organised set of instruction which includes:

- Content (what the AI needs to create)
- Style and tone (what it should look like or sound like)
- Format (measure, resolution or form)
- Use in context (for what system, audience)

In the case of multi-modal solutions, cues are shared across modality-tools. For example, a brand campaign may start with a text prompt to an LLM that drives prompts to the image, audio, and video generation tools.

Example Workflow:

- So we want to make a script for an advertisement that is thirty seconds long for a fitness app that is for young people.

The fitness app is what we are trying to sell to people.

We need to make the script fun and exciting so that young people will want to use the fitness app.

The fitness app should be easy to use. It should help young people get in shape.

We can show some people using the fitness app in the advertisement and they can be doing things like running and lifting weights.

The fitness app is a tool, for young people who want to get fit and healthy.

We should also say that the fitness app is available to download so that young people can start using it right away.

The fitness app is what we are trying to sell so we need to make it sound really good in the script.

professionals.”

- I want the Visual AI to make some pictures of people running in cities. The pictures should look like they were taken with a camera you know like regular photos. I am talking about high quality pictures of adults jogging in the city.
- Audio Prompt to TTS Tool: I want the advertisement script to be read out loud in an energetic female voice and I want her to sound like she is, from America.
- Video Prompt, to Video Generator: I want you to make a video that shows people jogging and has someone talking in the background. The video should have music playing and it should be thirty seconds long. I need this video to be a clip that will make people want to watch it. The video should have jogging visuals. The music should be upbeat.

Principles of Effective Prompt Engineering for Multi-Modal AI

## Consistency Across Tools

Prompts have to be able to strengthen the same brand identity as on text, images, audio and video output.

## Granularity in Instructions

Providing detailed cues avoids ambiguity. For instance by requiring “slow, formal narration” in an audio prompt will be enough to guarantee alignment with academic video.

## Iterative Refinement

As in single-modality use of AI, iterating is extremely important. When working on multi-modal projects, you may need to test prompts across a variety of tools and keep refining them until coherence is established.

## Interdisciplinary Thinking

Good engineers will need to learn the basics of story, design, sound, and tech format in order to integrate AI output effectively.

## Applications of Multi-Modal Prompt Engineering

- Education: Developing full e-learning modules comprising text descriptions, diagrams, narrated audio and tutorial videos.
- Medical (Healthcare solutions): Creating patient education materials, with simplified text and dispense of visuals, video demonstrations...
- Corporate training: Creating interactive learning experiences where scripts, visuals, audio-instructions and explainer videos can be produced together.

## Practical Example:

For example, a health care facility creating on content diabetes awareness may want to:

Employ an LLM to produce patient-oriented explanations of the disease state.

Somehow incorporate the image generation capabilities to make maps of how insulin works?

Employ audio generation for gentle vocal narration.

Create a motion graphic video showing life style advice for the patients.

Prompt engineering to ensure no one component overpowers the other, providing a well balanced educational tool.

## 6.1.3 Content Creation Across Modalities for Solutions

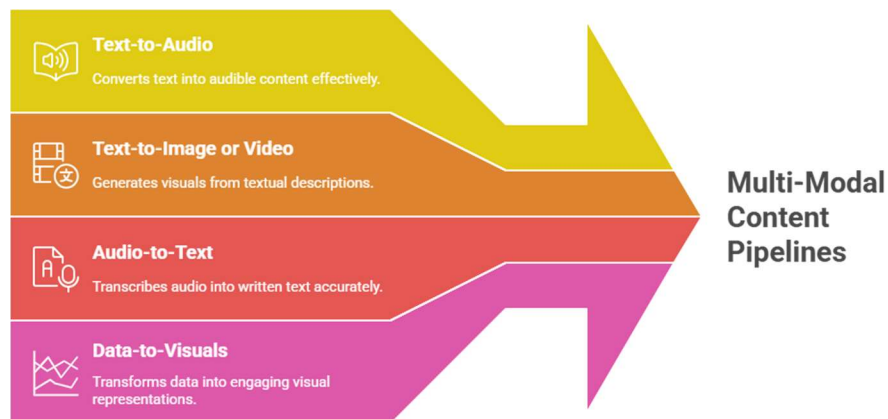

figure: **Multi-Modal Content Pipelines**

Content Generation and Cross Media Texts Networked knowledge is increasingly shaped as a network of multiple types, rather than being limited to texts in one format. What organizations increasingly really require are multi-modal content ecosystems, where snippets of the message or common solution are issued in varying formats across multiple channels. Management of AI tools is the key to this, opening the door for switches and transitions from one modality to another — text can be voice in a narrated podcast, images might turn into video clips, data takes the form of infographics.

Pipeline multi-modal content a13 Subsection 4.

#### Text-to-Audio

Additionally, we can input the text generated by LLMs into TTS (text-to-speech) systems to create audio versions of web- blogs/stories/learnings/newsletters e.g. Post-release you may have Cloze as an online course.

#### Text-to-Image or Video

AI-generated scripts and stories can be used as an input for image generators (e.g., MidJourney), video models (e.g., Runway Gen-2) to generate marketing content or explainer videos.

#### Audio-to-Text

Speech-to-text models convert podcasts, interviews or recorded lectures into written text. LLMs can then polish this information into articles, social media posts or study notes.

#### Data-to-Visuals

AI visualization tools can collate data from structured datasets to produce infographics, dashboards and explanatory diagrams.

#### Example Workflow

An organization focused on sustainability launches a campaign around adopting renewable energy:

- The ideal output that GPT could give me a research-based article like.
- Murf. ai turns the article into a podcast-like sound narration.
- Steady Diffusion makes companion infographics.
- Runway Gen-2 creates a brief marketing video on what has been discovered.
- The content is spread wide across social media, podcasts and classroom modules.

This is an example of how AI enables content continuity across ways in which audiences engage, extending reach and driving home the message.

### 6.1.4 Pitch Deck & Presentation Creation Using AI Tools

Pitch decks and presentations is an essential communications tool in academia, business and entrepreneurship. What they need is transparency, and persuasive narratives with production values. As you can see, the use of AI in this area allows to create these assets faster and makes them more polished.

#### AI in Pitch Deck Development

##### Script and Outline Creation

LLMs create slide-by-slide outlines in response to prompts like: “Draft a 10-slide pitch deck for an edtech startup raising seed funding.” The AI fills in a framework which includes problem, business value prop, solution, market space, business model and finances.

##### Slide Design

Tools like Beautiful. ai, Gamma and Tome AI Turns sketches into slides instantly by automatically picking layout, icons and typography.

##### Data Visualization

AI analytics tools generate graphs, chart and infographics which can be directly pasted into the decks.

##### Narration and Interactivity

TTS (text-to-speech) models can voiceover slide presentations, AI avatars can present the pitch in multiple languages.

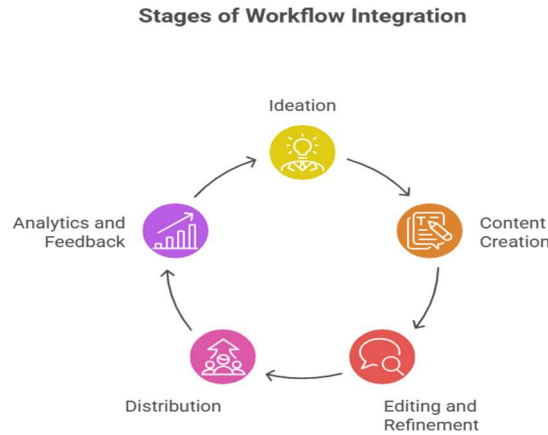

##### Example Use Case

For example, an entrepreneur gearing up for a venture capital pitch could: Notes.

- Utilize GPT to create a compelling story.
- Work with MidJourney to create images for product mockups.

- Use Canva Magic Design for slide design details.
- Include audio deck narration by Synthesia of an Avatar to allow the pitch deck to be interactive for remote investors.

This incorporation keeps the pitch deck professional yet multimodal, to cater for any audience.

Picture a Start-Up You are going to work on an imaginary start-up in one of the following domains: eco-friendly packaging, e-learning platform, AI tutoring app etc. Create a 5-slide pitch deck with the help of an AI:

- Extract representatives slide (outline) and fill in content of slides with a LLM.
- And now, you use design AI tool (for example: Canva Magic Design or Tome AI) to create visually stunning layout.
- Optionally, use TTS or avatar tool (e.g., Synthesia) to have narration on the deck.

Send us the deck and a brief (200-250 word) exegesis detailing how AI tools saved you time and resources, bettered quality of design, and augmented your ability to communicate your startup idea.

### 6.0.1 End-to-End Workflow Integration

Whole process automation of AI toolchains is called end-to-end workflow integration, a series of multiple AI tools that provide continuous pipeline for an entire process from ideation to production. This is the maximum extent of AI, where human labour world is so last season – Hello creativity and minimal disruption.

#### Workflow Integration Stages

Figure: Stages of Workflow Integration

## Ideation

LLM produce creative briefs, campaign plans or research problems.

## Content Creation

Text, image, audio and video models work together to create multi-modal assets.

## Editing and Refinement

The AI editing tools may clear up the air, correct grammar, modify sound quality or make visual layouts better.

## Distribution

AI-based scheduling and marketing tools help figure out when and where content should be shared.

## Analytics and Feedback

AI monitors engagement, captures feedback and compiles performance reports. Learnings from this phase are fed back into ideation, for a constant loop of refinement.

## Example Workflow in Practice

A multinational company bringing a new product to market might use AI as follows:

- Step 1: GPT autodrafts campaign brief and messaging.
- Step 2: MidJourney generates profile images while Runway Gen-2 creates teaser videos.
- Step 3: Murf. ai creates voiceovers for ads.
- Step 4: Canva Magic Design now groups them together into social media posts or presentations.
- Step 5: HubSpot AI-based platforms automatically publish, track engagement and creates a dashboard of analytics.

This demonstrates how AI toolkit can be harnessed into an end-to-end automation pipeline—and provide more than just incremental answers, but full-fledged solutions.

## Knowledge Check 1

Choose the correct option:

1. What is the primary advantage of integrating multiple AI tools into a workflow?
  - a) It ensures only text-based outputs are created
  - b) It reduces the need for prompt engineering
  - c) It allows for multi-modal solutions combining text, visuals, audio, and video
  - d) It eliminates the need for human involvement entirely
2. Which of the following best describes the role of LLMs in brand brief creation?
  - a) Generating only images for marketing campaigns
  - b) Drafting structured documents, analyzing consumer sentiment, and outlining strategies
  - c) Producing final pitch deck slides with embedded visuals
  - d) Editing video testimonials for brand promotions
3. Why is prompt engineering particularly important in multi-modal AI projects?
  - a) It avoids the need for iteration

- b) It ensures consistency and coherence across outputs in text, image, audio, and video
  - c) It reduces the cost of AI tool subscriptions
  - d) It guarantees outputs are always error-free
4. Which AI tools are most suitable for creating pitch decks and presentations?
- a) MidJourney and Stable Diffusion
  - b) Synthesia and Runway Gen-2
  - c) Beautiful.ai, Tome AI, and Canva Magic Design
  - d) Tacotron and WaveNet
5. What does end-to-end workflow integration in AI primarily achieve?
- a) Automation of the entire content lifecycle from ideation to analytics
  - b) Replacement of human creativity with AI outputs
  - c) Restriction of content formats to text-only solutions
  - d) Elimination of iterative feedback and refinement

## 6.2 Summary

v Interoperation between multiple AI tools enables workflows that cross -slice text, visuals, audio, and video to create multi-modal results rather than standalone outputs.

v Brands can leverage AI to write briefs, create case studies and campaign strategy, freeing up time from manual work and allowing more creativity.

v LLMs contribute to brand briefs with a prototype approach: they produce drafts in a structured way and provide insights about user sentiment or communication message. Combined with image or video AI, they are able to generate mood boards and campaign visuals.

v Case studies are brought to life with AI-written stories, AI-created infographics, and the like as part of the narrative.

v Research and analysis can be accelerated through LLM to summarize unstructured text, AI-based visualization of quantitative data, and sentiment analysis of customer feedback from digital channels.

v Multi-modal research workflows combine text, image and video generation tools for simulating, analyzing and disseminating findings in an integrated fashion.

v In multi-modal projects, prompt engineering is also important as prompts help maintain consistency across modalities. Guidelines need to include style, tone, structure and context for consistency between text/visuals/audio/video.

v Stimulate iteratively and interdisciplinary refined quality outputs using different tools.

- v Multi-modal based content creation can help the same message to be translated across text, audio, video and infographics to maintain consistency in all channels.
- v You can convert text to podcasts with TTS systems, datasets into visuals with AI visualization tools, or blog posts into short promotional videos using AI video tools.
- v AI tools make it easier to create pitch decks and presentations by composing content for slides, designing out slides, generating visual elements or even inserting AI avatars or voiceovers to present.
- v AI Empowers entrepreneurs, educators & corporates to build interactive, professional and persuasive decks in minutes.
- v End-to-end workflow integration Lets you automate entire pipelines--from idea to creation, editing, distribution and analytics with connected AI tools.
- v In commercial endeavors, such workflows may include creating drafts of LLMs, developing visuals and videos with creative AI tools, voiceovers with TTS systems and distributing content optimally using AI driven marketing platforms.
- v These integrated production processes save time and improve customization and efficiency but may raise ethical dilemmas about authenticity, transparency, and accountability for AI use.
- v Integration enables the users to participate not only as consumers of AI outputs but also as orchestrators of multi-modal ecosystems which offer end-to-end solutions.

## 6.3 Key Terms

- Multi-Modal AI – Combination of text, images, audio and videos to produce coherent results.
- Brand Brief – A guiding document for goals, audience and creative direction written or augmented with AI tools.
- AI Case Study – Evidence-based storytelling using LLMs, visuals and videos to highlight the success of a brand.
- LLM Summarization – Extracted key insights out of large amounts of research/literature using large language models.
- Prompt Engineering – This is the idea of carefully designing prompts to steer outputs in different AI modalities.
- Cross-Modality Content – that can convey the same message in different modes like text, audio, video and Infographics.
- AI Pitch Deck – A presentation made by AI itself, from drafting to design, visualization and even narration.
- End-to-End Workflow – AI powered pipeline from ideation to creation, through distribution and analytics.

## 6.4 Descriptive Questions

How does the combination of various AI tools improve the brand briefs and case studies?

How are LLMs used in research and analysis?

Why real-time engineering is crucial in maintaining consistency in multi-modal AI solutions?

Can you share a use case of how content transmutes across modalities with AI tools?

Why use AI in the pitch deck and presentation creation?

Describe what you understand about end-to-end workflow integration and its importance?

What are the ethics behind incorporating AI tools for multi-modal content creation/modification?

How can you apply interdisciplinary thought to advance prompt engineering for integrated AI workflows?

## 6.6 Case Study

### Leveraging Multi-Modal AI Integration for Scalable Content Solutions

- The demand for content is getting bigger and bigger. Businesses need to make content that's just right for each person. They want to use intelligence to make this happen. Companies are looking for ways to use AI tools together. They do not want to use each tool

They want to make content that has text, pictures, sound and video together. This makes the content more interesting and easier to understand. A company that helps businesses, with digital things tried using AI tools together. They wanted to make their work easier and better.

They used AI to make their brand information clearer and to do research faster. They also used AI to make their presentations to clients more interesting. The company found that using AI tools together made their work more efficient and consistent. They could deliver content to people quickly and it was all consistent. The company used AI to make their content and it worked.

#### Background

The consulting firm often made plans, studied cases and created pitch decks for its clients who worked in healthcare, education and technology. Usually people from teams worked on the words the design and the videos, by themselves which caused problems meant they did not always say the same thing and took a long time to finish. The clients of the consulting firm wanted to get plans, cases and pitch decks that included words, pictures and videos and they wanted to get them fast. The company wanted to solve this problem so they added some tools that use artificial intelligence including special computer programs called LLMs that help with writing and other models that create pictures and videos. They also used computer programs that can talk, like the ones that generate audio. They put all of these tools together to make it

easier to create content from start to finish. The company used these AI-driven tools, including the LLMs for drafting the visualization models for graphics the TTS engines, for audio and the video generation platforms to make this process work.

### Problem 1: Fragmented Brand Brief Development

Marketing teams spend a lot of time making brand briefs and creating mood boards. This usually results in the marketing teams saying things, about the brand and the campaigns are launched late. The marketing teams have to make sure the brand message is the same. The marketing teams want to launch the campaigns on time.

#### Solution:

The company used language models to make detailed plans for brand briefs based on what the clients wanted. Tools, like MidJourney that make images helped create boards that showed the mood they were going for. Other tools that make infographics summarized the information they got from researching the people who buy things. This made the process of making briefs go faster. Made sure the words and pictures worked well together from the beginning. The brand briefs and the way they were presented were better because of this. The company was able to make brand briefs that really worked for the clients.

### Problem 2: Inefficient Research and Analysis Processes

People who study data had a time putting together a lot of information from big datasets, market reports and what customers were saying. They had to do this work by hand. It took a long time usually several weeks. This made it hard to finish projects on time because the analysis of the data was taking long. The analysts were trying to turn all this information into something that they could actually use to make decisions. The data from the market reports and customer sentiment was very important, to the analysts.

Solution:

Literature reviews were summarized by Large Language Models and then Artificial Intelligence tools looked at the data and made trend charts and insights from it. The Visual Artificial Intelligence tools took the findings. Turned them into pictures that showed the information, which are called infographics. When it was time to give presentations the text-to-speech models read out loud the summaries so the insights from the Large Language Models and Artificial Intelligence tools were available to clients, in different ways.

Problem 3: Time-Intensive Pitch Deck Creation

Making a pitch deck is a team effort that involves writers, designers and presenters. This means it takes a lot of resources and time to get it done.

One of the problems is keeping everything consistent like the text, pictures and the story being told.

Solution:

The company used GPT-based models to make slide content for presentations. They also used Canva Magic Design to make the layouts look really good.. They used Synthesia avatars to tell people about the presentations, in many different languages.

This way of doing things made it a lot faster to create presentations it took 60 percent time. It also made the presentations look more professional and interesting for the people watching the GPT-based models and Synthesia avatars presentations.

## Reflective Questions

1. How can prompt engineering ensure coherence across text, image, audio, and video outputs in integrated AI workflows?
2. What are the risks of over-reliance on AI when creating brand case studies and pitch decks?
3. In what ways can end-to-end AI workflows improve client communication and project scalability?

## Conclusion

By adopting integrated AI workflows, the consulting firm successfully reduced inefficiencies, improved coherence across modalities, and delivered compelling brand briefs, research insights, and pitch decks at scale. This case demonstrates how multi-modal AI integration transforms traditional content creation into a streamlined, end-to-end process, empowering organizations to deliver consistent, high-quality solutions in competitive industries.
